SIR PHILIP WATTS, K.C.B., LL.D., F.R.S., *Vice-Pres.*

SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., *Vice-Pres.*

SIR HENRY TRUEMAN WOOD, M.A., *Vice-Pres.*

SIR ALFRED YARROW, Bt., M.Inst.C.E.

SECRETARY—G. K. MENZIES, M.A.

Secretary, Indian and Dominions and Colonies Sections—

SAMUEL DIGBY, C.I.E.

Accountant and Examinations Officer—J. H. BUCHANAN

Chief Clerk—GEORGE DAVENPORT.

Auditors—MESSRS. KNOX, CROPPER & CO

NOTICES.

NEXT WEEK.

WEDNESDAY, NOVEMBER 23rd, at 8 p.m. (Ordinary Meeting); PROFESSOR JOHN AMBROSE FLEMING, M.A., D.Sc., F.R.S., Albert Medallist, "The Coming of Age of Long-Distance Wireless Telegraphy and some of its Scientific Problems" ("Trueman Wood" Lecture). ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, will preside.

FRIDAY, NOVEMBER 25th, at 4 p.m. (Joint Meeting of Dominions and Colonies and Indian Sections.) A. H. ASHBOLT,

Agent-General for Tasmania, "An Imperial Airship Service." BRIG.-GENERAL LORD MONTAGU OF BEAULIEU, K.C.I.E., C.S.I., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

REPRINT OF CANTOR LECTURES.

The Cantor Lectures on "X-Rays and their Industrial Applications," by MAJOR G. W. C. KAYE, O.B.E., M.A., D.Sc., have been reprinted from the *Journal*, and the pamphlet (price 2s.) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W. C. 2.

A full list of the lectures which have been published separately, and are still on sale, can also be obtained on application.

DOMINIONS AND COLONIES SECTION.

The Council have appointed the Hon. Sir Edgar H. Walton, K.C.M.G., High Commissioner for the Union of South Africa; Mr. M. L. Shepherd, Acting High Commissioner for Australia; the Rt. Hon. Sir Frederick Lugard, G.C.M.G., C.B., and Sir Charles H. T. Metcalfe, Bt., members of the Committee of the Dominions and Colonies Section.

POSTPONEMENT OF PUBLICATION OF CHAIRMAN'S ADDRESS.

Owing to unavoidable delay in preparing the illustrations, it has been found impossible to print the Chairman's Address in this issue of the *Journal*, as was previously announced. It will, however, appear in the next number.

PROCEEDINGS OF THE SOCIETY

SECOND ORDINARY MEETING.

WEDNESDAY, NOVEMBER 9TH, 1921

MR. WILLIAM GRAHAM, LL.B., M.P., Member of the Medical Research Council, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Baillie, Andrew Francis, London.
Bliss, Ernest H., B.Sc., London.
Graham, Andrew MacIntyre, Liverpool.
Greaves, Richard Methuen, Portmadoc.
Lono, Albert James, Uxbridge.
Morris, Squadron Leader A. S., O.B.E., R.A.F.
Rogers, Captain Archibald Clement Campbell,
Tringganu, Federated Malay States
Symington, Harry, London

THE CHAIRMAN, in introducing Mr. Wilson, the author of the paper to be read that evening, said the members of the audience would agree that they were fortunate in having the services of Mr. Wilson to lecture on the subject of industrial fatigue. The present time was really one of transition from the economic conditions

of war to the economic conditions of peace, or at all events to the early economic conditions of the post-war period. The artificiality which had existed during the war was tending to pass away, and if the industrial conditions in almost any country in Europe were examined at the present time it would be found as a rule that those countries were doing their best to get back to some bedrock cost of production. Serious reductions of wages were everywhere being proposed, and in many cases adopted, sometimes with the substantial agreement of both sides in the industry and occasionally with a good deal of conflict. That was true of practically every European country, but it was, of course, necessary to make some exception—and that was very important in the case of Great Britain—where Germany was concerned. Germany had experienced recently an artificial boom in trade, due to certain currency conditions, the depreciation of the exchange and so forth, which had given her certain advantages in the export of her goods. It was perfectly plain now to everyone who had regard to the prevailing boom in speculation, which was true of Germany, that something approaching a crisis was coming. Many of the best thinkers in this country felt there would be a great reaction from that crisis on the industry and commerce in Great Britain, just at the time when that industry and that commerce were beginning to show some signs of a real revival after the depression of the past eighteen months. He thought everyone present would agree that if this country was to come through such a crisis successfully and if, above all, it was to regain the markets of the world which it had so far lost, its industry must be in every way efficient. Great Britain could not afford to tolerate much longer the undoubted waste that was taking place in a large part of its industrial system. As Mr. Wilson would probably indicate in his paper, the study of what was called in America "scientific management" was only just beginning in this country, and it would be generally agreed also that the investigation of such problems as the influence of temperature in the factories on industrial output, the response in the production of output to improved conditions of work, and a large number of other cognate problems, was also only just being undertaken. Personally, he deplored the recent tendency of the Treasury to reduce the already insufficient financial provision made for that work, and it was perfectly clear that, during the present period of economy, efforts must be made, both in the House of Commons and outside, to convince Members of Parliament that any large withdrawal of public or other funds from such work would prove to be an aggravated form of waste. Funds must be provided to enable the work to be continued, in the hope that the elimination of waste, both human and material, from the industrial system would be brought about, that the markets of the world would be

recovered, and, above all, that greater comfort and a greater contentment in industry would result, and at the same time British remuneration be safeguarded in what was probably the only sound way, namely, by the adoption of scientific methods. The remarks he had made were a very general and very vague introduction to the paper, but he was sure Mr. Wilson would regard them as sufficient for the purpose. Mr. Wilson had a very deep and wide experience of the problem on which he was about to address the meeting, and he had the greatest possible pleasure in calling upon him to read his paper.

The paper read was:—

THE WORK OF THE INDUSTRIAL FATIGUE RESEARCH BOARD AND ITS APPLICATIONS TO INDUSTRY.*

By D. R. WILSON, M.A., Secretary to the Board.

INTRODUCTION.

The present paper touches on an aspect of industry which until quite recently has been almost entirely ignored. Indeed, apart from a few sporadic experiments on the part of individual employers, of which Mather's trial of the 48-hour week in 1894 is in this country the earliest known example⁽²²⁾, no systematic attempt was made to study the human factor in industry in its physiological and psychological bearings until shortly before the war, when Kent conducted an investigation into industrial fatigue at the request of the Home Office⁽²¹⁾, and during the war, when many valuable contributions to the knowledge of the relation of hours of work to production, lost time, etc., were made by the Health of Munition Workers' Committee^(18, 19).

To study these problems on scientific lines, and in particular to continue the work already carried out by the Health of Munitions Workers' Committee, the Industrial Fatigue Research Board was appointed in July, 1918, by the Medical Research Council and the Department of Scientific and Industrial Research.

In planning their work, the Board decided to approach the subject referred to them from two directions: deductively, by means of investigation of industrial conditions that actually exist or have existed; and inductively, by means of research on fundamental principles. The latter work has recently been transferred to export

committees appointed by the Medical Research Council, and the present paper deals only with the industrial investigations.

These can be divided into two groups, i.e., those concerned with a given industry and those concerned with a given subject⁽¹⁷⁾. The Board have, for instance, completed or in hand extensive investigations into the tinplate, iron and steel, cotton, silk, laundry, boot and shoe and pottery industries. For the supervision of these they have set up special Committees, which representatives of the industries concerned are invited to join. At the same time, the Board have instituted research on special subjects, such as vocational selection and motion study, in individual factories where special facilities were offered.

Up to the present, the human factor in industry has received attention chiefly from two points of view, namely, the health of the worker and his safety, and no one can look back on the last 15 years without being impressed with the enormous advance that has been made in these respects. On the other hand, the physiological and psychological response of the worker to the conditions of his work has been almost entirely neglected, notwithstanding that this response is more sensitive than that of either his health or safety, so much so that the principal difficulty arising in its study lies in unravelling the tangle of the different conditions affecting him and ascribing to each cause its own effect.

One reason for this neglect is natural enough. A subjective phenomenon attracts notice to the extent that it is abnormal. Physiology is the property of the normal man, and physiological changes often remain unobserved and unstudied primarily because they are universal.

An additional reason is probably the fact that both the symptoms and causes of physiological disturbances are less apparent than those of the other factors already mentioned. In the case of industrial disease, the effects for the most part are distinctive, and, although the predisposing causes are often obscure, the direct cause can generally be detected, isolated, and made the subject of special research. Similarly, in regard to safety, not only is an accident an unmistakable occurrence, but the immediate cause can at once be identified and put right.

These distinctions, however, are not meant to imply that the work on which the Board is engaged is unrelated either to

* The numbers in brackets refer to list of the Reports of the Industrial Fatigue Research Board given at the end of the paper.

industrial medicine or to industrial safety, or that it should be regarded as a subject for isolated study. Unfavourable physiological conditions, if pronounced or long-continued, can readily impinge upon the sphere of pathology by causing disease; similarly, they can bring about a state in the worker which diminishes his immunity from accident. In addition, much of the Board's work is closely related to welfare; the two, in fact, have a common aim, amelioration of the worker's environment, the only difference being that in the one case this is treated from a physiological or psychological, in the other from a sociological aspect. The Board's work, indeed, marches with both industrial medicine and welfare, with rather indefinite boundaries between their respective spheres.

METHODS ADOPTED.

The healthiness of industrial work can be gauged by the absence of disease; its safety by the immunity from accident. What is the test whether or not the conditions are favourable from a physiological aspect? Three possible methods exist. First, unfavourable conditions may bring about the onset of fatigue in such a way that complete recovery at the end of the working period is not assured, with the result that accumulation of fatigue occurs as time goes on. In such a case, the effects of fatigue will probably be reflected in the sickness experienced or in the amount of time lost in the factory, and the physiological conditions of the work can be gauged through a study of these

Secondly, the fatigue experienced may stop short of this point and remain consistent with complete recovery on rest, and therefore with health. Here the above tests are clearly inapplicable, but if a subjective test could be devised giving directly a measure of the fatigue present at any moment, it would be possible by applying it to trace out the effects of the conditions and to study their variations. Unfortunately, in spite of several attempts, no such test has up to the present been discovered, and an indirect method of testing the physiological results of work has had to be used

Thirdly, unfavourable conditions may react in such a way as to impair the power of doing work; in other words, the worker is prevented from putting forth his best effort. This effect can be measured by

applying some test indicative of his "fitness," or, as it is generally termed, his "working efficiency."

The word efficiency is now used in so many senses that it is desirable to state at the outset its precise meaning here. Throughout this paper it is not to be taken as equivalent merely to *productive efficiency*, but as the physiological quality resulting from favourable conditions of work, of which increased production is only incidentally a symptom. This distinction is of real importance, as it is quite possible to speed up production for a short period with results that eventually turn out to be harmful.

Five main tests for "fitness" or "efficiency" have been used by the Board, though others have been adopted occasionally to meet special circumstances. These are:—

1. Variation in output.
2. Sickness and mortality.
3. Labour turnover.
4. Lost time.
5. Accident incidence.

1. *Variation in output*, whether over a day, a week, or a longer period, has been the most generally used, and provided that adequate allowance can be made for certain disturbing factors (such as incentive or technical changes), is probably the most trustworthy.

The advantage of this test is that it can be applied either by the collection of current data, i.e., by actual observation of the worker, or by the examination of existing records, and both methods have been adopted by the Board's investigators. There are, however, two limitations to the use of output as a test for fitness.

In the first place, it can only be applied to processes which lend themselves to measurement of output in terms of units, which are either constant over a sufficiently long period or are capable of being converted into a common unit by some simple calculation. Secondly, the sensitiveness of this test depends on the nature of the work, and in particular, on the extent to which the human factor plays a part in production. This varies from 100% in completely manual processes to almost 0% in completely automatic processes (?). For the latter kind of process output is obviously an unsuitable test, and another must be found before the worker's efficiency can be adequately studied.

2. *Sickness and Mortality.* So far as the investigations of the Board extend, they tend to show the fatigue now existing is non-cumulative and is normal rather than pathological. Its relation to health is, therefore, less pronounced than it was at the time when the Board was started. Nevertheless, the Board have paid some attention to this subject for three reasons.

First, physiologically unfavourable conditions, if inherent in a given occupation, may sometimes be reflected in the high rate of sickness and mortality for that occupation, as compared with the industry generally. Secondly, in industries involving exceptionally arduous work or subject to exceptional conditions of employment, the study of morbidity and mortality may suggest whether excessive fatigue, due to such work or conditions, actually exists, and if so, in which particular occupation (5). Thirdly, an abnormally high rate of sickness or mortality found in a given industry may in the absence of other explanation be *prima facie* an indication that such industry will offer a fruitful field for investigation.

3. *Labour Turnover.* Just as the bodily health of an industry is reflected in the magnitude of its sickness incidence, so is the "industrial health" of a factory reflected in the variations of certain phenomena, the study of which accordingly has a special practical bearing on fatigue and efficiency.

The first of these is "labour turnover" or the rate of change in the working staff, which may be used (with certain limitations) as a gauge or indicator of the internal conditions of a factory. A continuously high rate occurring in one department as compared with the factory generally may, for instance, be due to causes such as fatigue or ill-health produced by the work, unsatisfactory hygienic conditions, or faulty selection of workers for a particular task; an abrupt rise in the rate may indicate the introduction of a piece-rate which is regarded as unjust, or the appointment of an unpopular departmental manager or foreman. Which of the several possible reasons is the determining factor must, of course, be made the matter of special inquiry; estimation of labour turnover in itself can only indicate the need for such inquiry.

Broughton, Newbold and Allen, (13) following methods devised by Greenwood, have calculated the labour turnover in a number of factories, and have given a reliable and

sensitive method of estimating it. A characteristic feature of all the tables is the high rate of loss during the early months of service, emphasising the scope for vocational tests to discover the aptitudes of applicants for employment.

4. *Lost Time.* A second test of the "health" of an industrial organisation is the time lost on the part of the workers. Lost time was originally investigated by the Health of Munition Workers' Committee, in the expectation that it would throw light on the prevalence of fatigue during the war. It has been only occasionally used for this purpose by the Board (5), chiefly because it is not a suitable measure of the normal fatigue which for the most part exists to-day.

5. *Accidents.* A clear relation exists between efficiency and accident incidence, since the incurring of any accident involves lessened capacity, even though it may be so trivial as not to cause absence from work. Greenwood and Woods, (4) by the statistical treatment of accident records kept by certain munition factories, have adduced evidence to show that accident incidence is not wholly a matter of chance, but depends largely on some quality of susceptibility inherent in the personality of the victims. The further study of this important question is now under consideration.

In addition to these standard methods, several others have been used by the Board to meet special circumstances.

DIFFICULTIES EXPERIENCED.

A brief and necessarily incomplete description has now been given of the methods hitherto adopted by the Board to measure the fitness or efficiency of the worker, with a view to discovering, not whether his productive capacity is at a maximum, but whether his environment or other conditions of work are physiologically favourable. Before proceeding to an account of the results actually obtained, it may be desirable to mention some of the principal difficulties experienced in our work.

Human efficiency is influenced by a large number of conditions functioning simultaneously. There are, for instance, temperature, humidity, lighting, various technical considerations (such as change of type of work), labour turnover, conditions outside the factory (such as housing, food and transport), at the present time variations

in working hours caused by the abnormal conditions of trade, and finally the individuality of the workers themselves. Theoretically, in order to ascertain the effects of any one condition (such as temperature), it is desirable that that condition alone should vary, all other conditions of work (such as arrangement of hours, product of manufacture, social circumstances of the worker) being constant. In field investigation, however, circumstances, as a rule, cannot be made to order, but must be accepted as they are, and it is very rarely that the above arrangement can be realised even approximately in practice. Usually, therefore, the Board have had to be content with conditions which lend themselves to treatment with approximate truth after the application of certain corrections. It is impossible to go into these fully here, but as examples, works as homogeneous as possible can be selected for comparative study, units of production can sometimes be expressed in terms of a common unit by suitable conversion formulæ, minute data can be collected and those constant in regard to a given variable extracted for special study, mass data can be obtained and assumed to represent average conditions, etc.

A second difficulty has been the uncertainty of how long existing conditions would continue in any research undertaken. In normal times, the hours worked and their arrangement might have been anticipated as being one of the few constants the Board would have to deal with. Since we started work there have been no fewer than three abrupt changes in this respect. Our work was begun at a time when long war hours existed in most industries; then came the Armistice, followed by a general shortening of hours; finally, for more than a year, short or irregular time has been worked in many industries, and conditions have become altogether abnormal.

A third obstacle has been the difficulty in discovering suitable raw material for our work. For instance, there must exist throughout the country a mass of records of different kinds which only require working up in order to throw most valuable light on the problems on which we are engaged. Employers often are naturally unconscious of their value in this respect, and it is generally only by chance that they have been brought to our knowledge.

One difficulty we have *not* experienced has been the obtaining of facilities for research, and it is pleasant to testify to the extent to which we are indebted to the co-operation of both employers and workmen. Employers whom we have approached have, without exception, placed the whole of their information at our disposal, have continually helped us with advice, and in several instances have made experimental alterations in their works in our interests. Workmen, again, when once they have understood the object of our work, have helped us in every possible way, often to the extent of devoting a considerable part of their spare time to our interests.

EXAMPLES OF RESULTS OBTAINED.

The results obtained in the different industrial investigations of the Board may be regarded as falling into three categories, according to whether they relate to:—

- (a) *Hours of labour*, including spells, rest-pauses, etc.
- (b) *Other conditions of employment*, or the physical conditions of the workers' environment, constituting the *im-personal* factors in efficiency and fatigue. These include temperature, humidity, ventilation, lighting, dust and vibration.
- (c) *Methods of work*, constituting the *personal* factors in efficiency and fatigue, such as vocational selection, motion study, seats, machine design, etc.

HOURS OF LABOUR, ETC.

The pioneer work in this country on the relation of hours of work to fatigue was carried out by the Health of Munition Workers' Committee (18, 19). The false economy of hours of work above a certain length was then clearly demonstrated by Vernon, who found that the long periods of employment introduced ostensibly to bring about increased production resulted in many processes in such a reduction in hourly output as more than to counter-balance the additional time available for production, so that the total output was actually less than when the hours of work were subsequently reduced.

The work of the Board deals largely with variations in output over a given period.

(a) *Variations in Output during the Day.*

A study of variations in output at short intervals such as an hour is of interest for the tracing of typical work curves for different kinds of work, and for indicating the existence of fatigue at the end of the day.

Fig. 1 relates to the hand-charging of blast furnaces on the 8-hour shift system (5).

investigations (mostly in reports not yet published), and was found to be representative of engineering work by the American Committee on Industrial Fatigue both for an 8-hour and a 10-hour plant. Probably, therefore, it may be taken to be typical of work over a short period.

The difference between the curves in the two figures is also of interest. Hand

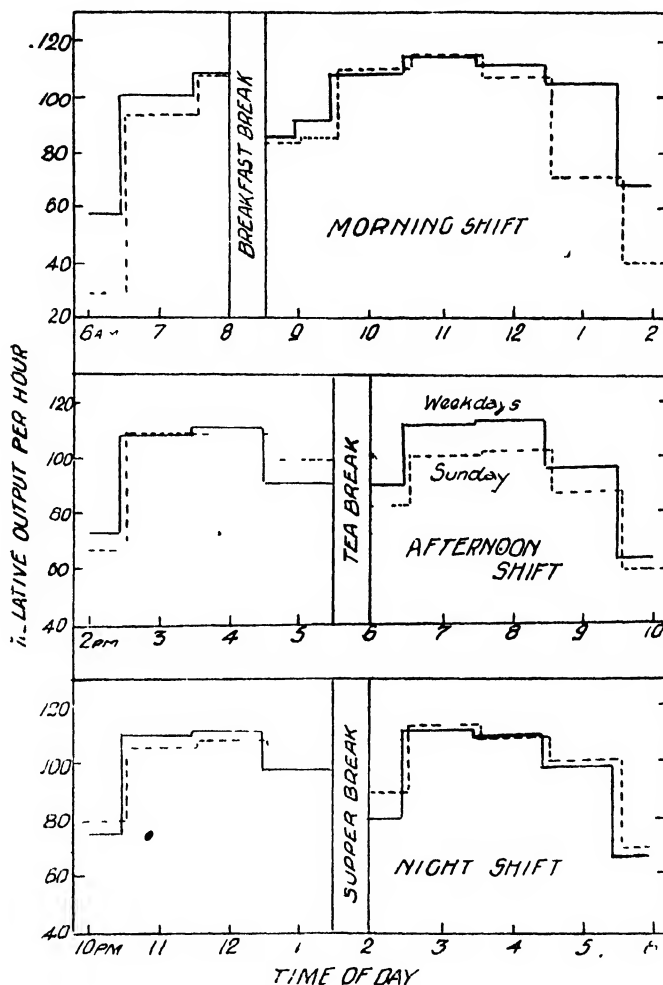

FIG. 1.—Hourly rate of charging blast furnace.

Fig. 2 relates to the weaving of two kinds of silk during a period free from certain disturbing factors (9).

It will be seen that these curves conform to the same general shape. Both show a rise at the beginning of the work-period and a fall at the end, and similar but smaller rises and falls occur with each spell. The same type of curve occurs in many other

charging being a completely manual process shows a far greater rise and fall than silk weaving, in which the human factor probably plays a part in production of only about 15 to 20%.

(b) *Variations in Output during the Week.*

The variation in daily output throughout the week can be used as a test whether

FIG. 2.—Variation in rate of output throughout the day. (Silk weaving.)

fatigue is physiological or pathological, in other words, whether there is complete recovery during the night's rest.

Fig. 3 contains sample curves relating to different industries (⁹, ¹⁰, ⁵).

It will be seen that they contain no evidence of cumulative fatigue, since the rate of output shows no *progressive* decline throughout the week.

One interesting point about these curves is that they assume the same general shape as the daily output curves. There is the same rise at the beginning (the so-called

Monday effect) and the same fall at the end.

In view of this similarity, it is tempting to suppose that human performance may be dependent on a number of superimposed rhythms corresponding with the periods of work, beginning perhaps with the rhythm of the actual movement and ending with a seasonal rhythm. The suggestion, indeed, has been made that these performance curves are rudimentary approximations to the resultant of various sine-curves, representative of periods of different lengths, just as a stretched string vibrates both in its whole length and in its aliquot parts.

Evidence of the presence of some innate diurnal rhythm in certain kinds of work is afforded from experiments carried out by Muscio on women medical students (²³). The subjects were divided into two groups (B₁ and B₂), one of which was engaged in continuous academic work whilst the other underwent complete rest. A series of mental tests was applied to each group every hour from 10 a.m. to 5 p.m. on two days, B₁ resting and B₂ working on one day and B₂ resting and B₁ working on the other. The results are given in Fig. 4:

FIG. 4.—The broken lines are the resting groups, the solid lines the working groups. Ordinates indicate group averages. The two upper curves refer to Nov. 7th, the two lower curves to Nov. 6th. (Practice accounts for the fact that the curves for the 7th are above those for the 6th.)

FIG. 3.—Variations in output throughout the week.

It will be seen that the variations in the marks obtained (corresponding with output in industrial work) follow the same course in the resting and working groups, the difference between them being roughly constant. Further, for the greater part of their course all the curves show a marked similarity to the "saddle back" type of curve which seems to be typical of industrial work.

(c) *Variations in Output of Longer Periods.*

In addition to variations in hourly and daily output, variations over longer periods, such as a week or a month, have been studied in certain industries. These are of special value in enabling us to trace seasonal influences and to compare the effects of different systems of employment.

Seasonal Variations. - Vernon has shown that in heavy work, especially when it in-

FIG. 5.—Variations in rate of output over a period of 12 weeks from Dec. 15th to Mar. 6th (Silk weaving).

volves exposure to high temperatures, output undergoes a consistent seasonal variation, being, with very few exceptions, greater in winter than in summer. The data collected by him ^(1, 5) are summarised in the following table:—

TABLE I.—*Seasonal Changes of Output.*

Occupation.	Relative Output during		
	Winter.	Spring and Autumn.	Summer.
Men charging blast-furnaces	105.0	106.5	88.5
Open hearth steel melters	107.7	102.0	96.2
" "	85.7	85.1	84.8
" "	102.5	100.5	97.2
" "	102.5	104.6	102.8
Rolling mill men	107.0	106.5	107.0
" "	124.0	118.0	111.0
" "	105.2	98.4	96.5
Men puddling iron	104.7	102.2	96.0
Tinplate mill-men	103.3	99.9	96.9
Mean temperature at Greenwich	40.0°	48.5°	60.2°

Those figures show that with few exceptions the lowest output occurs in summer and the highest in winter, with intermediate values for the spring and autumn.

The variation in the opposite direction

was clearly traceable in the process of silk-weaving ⁽⁹⁾, as is shown in Fig. 5.

Except for the abnormal Christmas week and the week preceding Christmas, there is a practically continuous increase throughout the period. As will be seen later, this effect is to be ascribed largely to the gradual reduction in the use of artificial light.

Effects of Different Systems of Employment.—As an illustration, the effect on output of a reduction in hours in steel-making may be quoted. Fig. 6 gives the output of 10 steel furnaces over a period of four years ⁽⁶⁾:

In June, 1912, the men went on to 8-hour shifts, and for the first two months there was no definite improvement in output. It then increased rather irregularly until July, 1913, or 13 months after the change had been made, when it again fell away considerably for some unexplained reason. If the dotted line (representing a rough average) be taken as a criterion, the reduction of hours was followed by an increase in output of about 18 per cent.

CONDITIONS OF EMPLOYMENT, OTHER THAN HOURS OF LABOUR, ETC.

In the Board's investigations some information has been gained as to the relation between the worker's environment and his efficiency, especially in regard to temperature, humidity, ventilation, and lighting.

Temperature.

One illustration of the effect of temperature on output has been already illustrated by the seasonal variations which occur in

FIG. 6.—Output from steel furnaces.

the case of hot and heavy work (see Table I.).

Vernon has also adduced evidence to show that in tinplate manufacture the rate of output is greatly influenced by the temperature of the environment, and estimates that in one factory the output of the shifts during the hottest weather was as much as 30 per cent less than during the coldest weather⁽¹⁾.

Humidity.

Vernon has shown that in tinplate manufacture the efficiency of the worker seems to be related to the air humidity, being greater when the relative humidity of the air is low⁽⁴⁾.

Ventilation.

In considering the effect of ventilation on efficiency and fatigue, the particular aspect concerned must be clearly defined. The change of air in the environment (if we may so define ventilation) may be regarded from different points of view in respect of its effects on the workers. Pathologically, it may be considered as a vehicle for the removal of dust or of the germs of infection, physiologically as a stimulus to muscular activity, and psychologically as a means of reproducing to some extent the invigorating conditions of outside air. The work hitherto carried out by the Board is concerned with the second of these effects, and in particular the cooling power of moving air.

Some striking results in this respect were obtained by Vernon in the tinplate industry⁽¹⁾. Some of the rolling mills were provided with artificial means of ventilation, such as paddles or air douches, whilst others simply depended upon natural means. The difference in the seasonal variations in output (see above) between the two kinds of mill is clearly shown in the following table:—

TABLE II.—*Comparison of Output in Summer and Winter (Tinplate Manufacture).*

Factory.	State of Artificial Ventilation.	Mean Output in		% Reduction in Summer.
		Dec. & January	July & August	
A.	Good.	100.5	97.5	3.0
B.	Moderately good.	102.5	97.0	6.4
C.	Moderate.	105.5	94.5	10.4
D.	None (good natural).	104.5	93.0	11.0
E.	None (poor natural).	108.0	93.5	13.4

The effect of the good ventilation is clearly reflected in the evenness of output in Factories A. and B. compared with Factories D. and E.

The extent to which atmospheric conditions vary in their physiological effects has been explored by Hambly and Bedford⁽¹¹⁾ in a number of boot factories by means of the kata-thermometer, an instrument designed by Leonard Hill⁽²⁰⁾, to measure the cooling power of the air, and similar observations have now been collected in the cotton weaving, laundry and pottery industries. The correlation of the conditions observed with fatigue and efficiency is, however, not yet complete.

Lighting.

The effects of lighting on production have been studied by Elton in silk-weaving, a fine process specially susceptible to variations in illumination. Table III. shows the distribution of output (corrected for certain variables) from 56 looms during the week ended December 20th, 1919:—

TABLE III.—*Distribution of Output through the Day in Winter (Silk-weaving).*

Period (a.m.)	Hourly output.	Period (p.m.)	Hourly output.
7.30 - 8.30	45.8	1 - 2	47.5
8.30 - 9.45	49.3	2 - 3.15	52.1
9.45 - 11	52.1	3.15 - 4.15	50.9
11 - 12	48.3	4.15 - 5.15	41.9

The use of artificial light was confined to the first and last periods, and to this must be attributed in great part the heavy drop in output observed, since at a later season when artificial light was no longer used, the reduction in output at the beginning and end of the period of employment, though still present, was much less marked. Elton concludes that under artificial illumination production falls, even if electric light of sufficient intensity is provided, and that the magnitude of this fall is of the order of 10 per cent. of the daylight value of the rate of output.

METHODS OF WORK.

The results hitherto described have been based almost wholly on mass data; that is to say, inferences have been drawn on the assumption that with a sufficient number of observations chance irregularities such

as those due to the personality of a particular worker will tend to cancel one another and that the results will in fact represent actuality. There is, however, one important section of the Board's work where this method of procedure is impracticable at present. The *method* of doing work is so much a personal characteristic that any progress in this respect can only be expected from an intensive study of individuals.

The part played by the worker himself has no doubt as important a bearing on his efficiency and fatigue as the impersonal factors already dealt with. This has, in fact, already long been realised in the United States, where Taylor, Gilbreth and others have raised the study of the personal factor in industry to the level of a definite science. In this country little has yet been accomplished on these lines, though a proof that interest in the subject is awakening is shown in the formation of the National Institute of Industrial Psychology, a self-supporting organisation formed to study and give practical effect to these principles.

It is important that the attitude of the Board towards this side of their work should be clearly defined. Briefly it may be expressed by saying that the methods of work have been studied with the primary object, not of securing increased production, but of increasing the *ease* with which a given task can be carried out, first by ensuring that the conditions under which the worker works place no unnecessary obstacles in his way, and secondly, through the proper development of the latent capacities possessed by the worker himself.

The former of these stages includes such questions as the relation of machine design to human requirements, and the type of seats and benches provided for the work. Wyatt, (8) for instance, shows that certain types of winding frames in the cotton industry involve less stretching and bending on the part of the operative than others.

The second stage, namely, the development of the capacity of the worker can be treated from two points of view. First vocational selection can be applied, and in this way a worker may be deterred from undertaking a task which is naturally uncongenial to him, and may be transferred with little waste of time to one in which his natural aptitude can be utilised. Secondly, means can be taken by the introduction of time and motion study to ensure

that the completion of the task is carried on with the minimum expenditure of effort. Vocational selection, therefore, may be regarded as an antecedent to employment, motion study as a suitable method of training after employment has been accepted. For these reasons the Board have regarded both vocational selection and motion study as within their scope, and as a first step have decided to publish reports containing summaries of the work hitherto done in both subjects (12, 14).

It is impossible in the present paper to enter fully into this side of the Board's work, interesting as it is, since most of the reports dealing with it are still in the press,* but at an early stage of their existence the Board were brought into touch with one factory in which a very complete system of motion study had been in force (an iron foundry) for some years. As a result of this system both the output and the earnings of the men (in spite of a reduction in hours) rose enormously.

Since this report was issued two investigations (11, 15) based on motion study methods (in a confectionery factory and in a metal polishing factory respectively) have been carried out by Farmer, and these also indicate the vast possibilities of such methods if properly applied in increasing human efficiency in industry.

Similarly, considerable research has been carried out on vocational guidance, and a report containing three studies on the question (one an investigation of the "capacities" required by the hand compositor in printing, the others inquiries into certain physical characteristics in relation to selection) will shortly be published (16).

THE FUTURE

The policy of the Board hitherto has been to devote the greater part of their resources to the general study of certain industries, in other words, they have concentrated on the industry rather than on a given subject for investigation. They have done this with a twofold object first in order to instruct themselves and to extract from an industry as much knowledge as possible bearing on general principles, and secondly to make a beginning in the development of the study of the human factor and in the practical application to industry of the results of research.

* A few of the principal results obtained were illustrated at the lecture by means of lantern slides.

The field of work, however, is a very large one and little real expansion can be expected so long as its study is left entirely in the hands of a central body with limited funds, whose activities have been recently seriously curtailed owing to the need for national economy. Real progress can only be made if industries themselves will agree either to co-operate with the Board or to undertake similar work on their own responsibility.

Obviously, the Board, with their small staff of investigators, cannot do more in any one industry than indicate by means of preliminary work the lines on which research can be profitably continued, and the time has now arrived when, if work of this kind is to be firmly established, industries themselves must participate in it by assuming part of the responsibility for the supervision and the financing of the work.

Co-operation of this kind would have a double advantage. In the first place, it would ensure adequate and informed criticism of our work, and that industry itself would be the judge of its results and benefits. Secondly, it would tend to eliminate one cause of criticism alleged against us, which I am bound to say has undoubted substance, namely, that in our work the technical and mechanical factors have not always been given their due weight. Our work already requires many qualifications, and our investigators obviously cannot as well be technical experts in every trade they investigate. We have tried to overcome this difficulty by inviting the assistance of representatives of the trades concerned to criticise our reports before publication, but in spite of the invaluable help given us, this is not the same thing as having a technical man to take part in the actual work of investigation.

How can these difficulties be remedied? I suggest that Associations for research on the human side should be formed, similar in some respects to existing Research Associations, but with two important differences. In the first place, I regard it as essential for the success of such work that the responsibility for initiation and supervision should be shared equally between the employers and the workmen, acting together. The associations in question, therefore, should be joint bodies, composed of employers and representatives of the workers, with an elected chairman. Secondly, each association, instead of being confined to a single

industry, might with advantage be constituted so as to be representative of a group of allied trades. In technical and material research, the questions dealt with affect as a rule only one particular trade. In research of the kind on which the Board is engaged, most of the problems have a more extensive application, and a wider unit of grouping can be adopted. In the textile trades, for instance, most of the processes have a family likeness and differ in detail rather than principle, so that many of the problems arising are of common interest to all the trades. Economy, therefore, as well as greater opportunities, would be secured by combining the whole of the textile trades into a single group, and forming the association from representatives of all the component industries.

Subject to these conditions, there are many alternative courses open. The association might, for instance, be formed entirely of members of the trades concerned, and conduct their own investigations with any help they desire from the Board, or they might be constituted of members of the trades, plus members or nominees of the Board, which is the method we have hitherto adopted. Again, they might engage their own staff for exclusive work for the trades, or they might engage merely the subordinate workers, responsible for the collection of data, calling on a senior investigator of the Board to direct the lines of research. These are matters of detail compared with the general principle that for real and lasting success the supervision of research of this kind in its practical aspect should be in the hands of an association composed predominantly of industrial representatives.

Research of this kind is not expensive, as it involves practically no capital outlay in the way of laboratories or expensive plant, and almost the whole of the cost would be the salaries and expenses of the investigators.

PRACTICAL BEARING OF THE WORK.

In research work of this kind there is necessarily a stage during which progress is slow, and some time must still elapse before the full results of the Board's work can be translated into practice. The Board, indeed, have hitherto refrained from starting research solely with the object of arriving at immediate practical results; they have instead preferred to study the more funda-

mental issues in the expectation that any practical applications hereafter made may be on sure ground. Nevertheless, it is, perhaps, desirable to meet the possible contention that most of the results so far obtained have merely a theoretical interest, and that industries themselves should not take part in the work until its practical possibilities are more clearly seen.

First, I claim that the work of the Board is the first systematic attempt to ascertain *facts*, which can be used for defining numerically the most favourable conditions of work. The restrictions on hours of employment in successive Factory Acts have been largely the result of compromise between many opposing opinions, and no scientific evidence is even now available to indicate the best arrangement of hours of work of different types. Here alone is a large and most valuable field of work still to be explored.

Secondly, I claim that the work of the Board has a direct and important bearing on increase of production, an increase to be brought about not by any artificial incentive or by appeals to the workers, but by increasing the *ease* with which work can be carried out through obedience to the natural laws of human effort. To take only one example; it has already been shown that the daily and weekly output curves conform to a certain type, which may, perhaps, be the embodiment of some law of rhythm. Is it not possible, by comparing the output curves for the same work done under different arrangements of hours, to determine which particular arrangement indicates the most favourable response on the part of the worker?

Thirdly, I claim that even after the short time the Board has been in existence, many matters have in fact been discovered deserving of immediate attention on the part of the trades concerned. It is impossible to go more fully into this question here, as the points referred to have generally an interest for one special industry, but almost every one of the Board's published reports contains practical suggestions based on actual observation, which could be usefully considered by an industry with a view to immediate application.

Finally, my experience has convinced me that the work of the Board, so far as it has advanced, has had an indirect effect which is, perhaps, not less important than its contributions to knowledge. As

already stated, in each of our industrial investigations we have received the help of employers and workmen nominated by the trade concerned. They have met on new and common ground, and it has been very striking to notice the mutual goodwill and the real interest taken in our work throughout by both alike. One reason for this, I suggest, is that industrial life is being viewed from a special angle, whereby employers and workmen get a new insight into one another's difficulties. For this reason alone, the continuance and expansion of the work that we have begun would, I am convinced, be of great value.

DISCUSSION.

MR. ARTHUR PUGH (Secretary, Iron and Steel Trades Confederation) said he was sure everyone present had listened to the paper with very great interest and had derived much information from the slides which the author had shown. Personally, he was particularly interested in the subject, because the Industrial Fatigue Research Board had done a considerable amount of work in connection with the iron and steel trades. The members of those trades felt very grateful to the Board for the services it had rendered them by the publication of the excellent reports of Dr. Vernon in regard to the effect of industrial fatigue on output in the iron and steel trades, and they were most anxious that the work of the Board should be continued, because they knew from practical

experience how much the particular matters which had the attention of the Board entered into the everyday life of the workers in those trades, which were generally arduous trades. If the knowledge which the Board had acquired and the experience of those connected with the Board could be conveyed to those engaged in the iron and steel industry, he was sure it would have good results not only for the workmen but for the industry as a whole and all concerned in it. Those who were engaged in the workshops knew how greatly the little things which affected the workman in his employment entered not only into the question of production but also into the question of the contentment of the workman, and they also knew the psychological effect which the little inconveniences existing in the factory or workshop had upon the workman. Those matters had a considerable effect upon output and upon the whole success or otherwise of the undertaking. It was surprising how little those matters were noticed, and it was only when one had actual workshop experience that one understood how important it was that the conditions of the workshop and the psychology of the workman himself should be studied, and that everything should be done to make the conditions of the workshop as satisfactory as possible. He was particularly struck in visiting a tinplate works one day, in connection with some proposals that his Confederation were submitting for the consideration of the Industrial Council, to notice the number of little things that had contributed very much to the comfort of the workshop, such as devices to prevent unnecessary lifting and to reduce the heat of the furnace. The mills to which he was referring had been operated by the double roll system, in order to find employment for old men, who had left the trade, when the younger men were serving in the Army. The same conditions and the same method of working were continued in the mill after the war was over and the young men returned. The result was an astonishing increase of output, which was attributed almost entirely to those little improvements. Practical experience of the workshop showed that much might be done in that way. In iron and steel works there were often found impure air and unsatisfactory ventilation. It was astonishing to find the difference in comfort produced by working in a shop with a high roof as against working in one with a low roof. The temperature of the workshop affected the men's tempers very often, and the general contentment of the men reflected itself in their output. He was perfectly certain there was a very great field for the work of the Board. When the Board was established those interested in the subject looked forward to great progress being made, and thought: "Here is the Government, as representing the community, really interesting itself in industrial conditions. It is going to employ men with

scientific knowledge, men who have studied various scientific questions, and that knowledge is going to be applied in order to see that it shall not be said in the future that we are a C3 nation." He was sure that so far as the Trade Unions were concerned they thought a great deal would be done. Everyone concerned was very much disconcerted when it was announced that on the ground of economy the Board's work was to be restricted, but he agreed with the author that the industries should do a great deal in the matter themselves. He felt sure that, if the Board continued its work and an endeavour was made to bring to the attention of the organised employers and the organised workers the immense advantages which would accrue from the development of the work and their co-operation, the work could be developed to the general advantage—to the advantage of industry, the advantage of the workers, and the advantage of the community. He sincerely hoped that at least the work would not be further reduced and that it would receive Government support, but most of all he hoped that the industries themselves would take the matter up. He was certain that, so far as the iron and steel trades were concerned, having regard to the excellent work the Board had already done for them, anything they could do to extend its operations and to give it support would be willingly done.

DR. D. A. COLES (Medical Officer to the Gas Light and Coke Company), after congratulating the author on his excellent paper, asked if any record had been made as to the difference of output between those who were employed on piece work and those who were employed on time work, and also whether any record had been made with regard to the output of those who were co-partners, those who were ordinary workers, and those who were merely casual workers.

MR. WILSON said the Board had not specifically dealt with the particular points that Dr. Coles had raised. They had to take the opportunities as they occurred, and they had now only limited facilities for work, a reduced staff and so forth. If the present staff of the Board could be multiplied by ten, there would be plenty of work for them to do. He was very grateful for Dr. Coles' suggestions and would bear them in mind. With regard to the results he had shown, many were not yet published, but most of them were contained in Reports which were now in the press and would appear in the course of the next few weeks. The titles of the Reports would be included in the list of references that would appear at the end of his paper when it was published.

MISS K. MACLEAN, speaking as a representative of a women's industry, laundry work, said the people she knew in that industry very much appreciated the careful investigation that had been made amongst them. She had worked on a board alongside her women for the past eighteen years, and she could say from experience that the work entailed extreme fatigue, whilst the hours of work were very long. Any suggestions for improving the conditions that might be contained in the Report with regard to the laundry trade, which she hoped would soon be published, would be very much appreciated by the trade. The laundry trade was about to form a Research Society for the investigation of all kinds of technicalities and she thought it would prove of great advantage if something could be done to bring before the notice of the employers in that trade the details which the author had given in his paper.

MR. PUGH asked if any attempts had been made to invite the co-operation and support of employers generally throughout industry in connection with the work of the Board.

MR. WILSON, in reply, said the method he advised the Board to adopt was to conduct some initial research in a certain industry and then to approach the employers and the Trade Unions in that industry and ask them to co-operate with the Board. Personally, he thought there was not yet sufficient knowledge of the work of the Board for any general appeal to be made to the whole of the industry of the country with any prospect of success.

MR. PUGH said considerable interest had been awakened in the subject by experiences during the war, and that interest might become less and less if it was not maintained by the Board. In order to do that, should not the Board get into touch with employers' organisations, Trade Unions, and so forth? The present might perhaps be a somewhat critical time for the Board itself.

MR. WILSON said he was now actually in negotiation with several industries on the subject.

MR. J. HERBERT PARSONS, C.B.E., F.R.S., asked if the matter was not largely a question of publicity. He thought one of the greatest advantages of the paper was that it had been read before the Society and that it emphasised the valuable work which the Industrial Fatigue Research Board had performed, and it ought to have greater publicity even than that which would be effected by its publication in the Proceedings of the Society. It would be of benefit if abstracts were published elsewhere, so that the work of the Board would become better

known. As one who had nothing whatever to do with industry but something to do with science and a certain amount to do with some of the Committees which were appointed for various specific purposes, it seemed to him that the Industrial Fatigue Research Board deserved support on a much wider basis than the immediate work which it did. It was an object lesson in the combination of scientific work and the utilitarian aspects of scientific work, and he thought that was a lesson not only to the industries, which were frequently accused of not adopting scientific methods, but also to the pure scientists, who were liable to work on such purely scientific lines that they did not appeal to the practical people. It was to the detriment of the purely scientific workers themselves not to be brought into close contact with the actual workers. It was an old established theory, which had received the support of the greatest scientists, that the results of the most practical utility were derived from work which was not necessarily directed to a utilitarian end. There was no question that that was true, but there was reason to think that it had been emphasised rather too much. During the war utility was to the fore. Scientific workers were brought into the factories and a great many of them found themselves very much at sea, but it did them a tremendous amount of good to be brought into direct contact with practical utilitarian questions, and they rose to the occasion extremely well. For those reasons it was advisable that the Industrial Fatigue Research Board should be advertised as an object lesson. Those who were dealing with purely scientific matters were not surprised to find that one of the first economies effected by the Government was the cutting out of the absurdly small amount of money that the work of the Board required. That surely was attributable to the fact that, generally speaking, the politician's education had been neglected from the point of view of scientific matters. In saying that he was speaking quite seriously, and he thought many politicians themselves would admit it. If the Industrial Fatigue Research Board was thoroughly well supported and did valuable work and tended to produce greater amenability amongst the workmen and the industrial employers themselves and had beneficial results, it would be a very valuable means of educating the politicians.

PROF. E. L. COLLIS, M.D., speaking as one who had been interested in the subject of industrial fatigue research from its very inception, said he wished to thank the author for the way he had presented that evening a great volume of work. After listening to the results he had presented, it was difficult to realise that it was only in 1916 that the Health of Munition Workers Committee issued its first Memorandum, in which it summarised the thoughts that were

in the minds of those who had interested themselves in the subject of industrial efficiency and fatigue. It was only after the issue of that Memorandum that an attempt was made to ascertain facts, so that there might be something on which to advise the Ministry of Munitions how it should handle the labour upon which the fighting forces then entirely depended for the output of munitions. Since that time, 1916, there had been many vicissitudes. The work of the Health of Munition Workers Committee came to an end, an interregnum occurred, and then the Industrial Fatigue Research Board was appointed and carried on its work with some of the results which the author had portrayed. The Board had had many vicissitudes, many changes and many struggles—such as Mr. Parsons had touched on—to maintain its existence, and yet it had achieved the results of which the author had spoken that evening. Those results were due in a great measure to the author himself, who had in his paper belittled his own services in paving the way and smoothing down difficulties so that the observations could be made and the data and records accumulated. In thanking the author for his account of the work of the Board, he wished also to thank him personally for the great work he had done. It had already been pointed out that the so-called economy of the Government had limited the activities of the Industrial Fatigue Research Board. Any single one of the investigations the Board carried out would probably increase the efficiency of the workers in British industries to a sufficient extent to return to the Chancellor of the Exchequer more than the whole expenses of the Board in a year. He hoped if there were any people present who could make their voices heard in the deliberations of the Empire they would see to it that such a form of economy was not adopted. He had been particularly struck by one point in the paper, namely, that the whole endeavour of the Board had been to see what could be done to ameliorate the conditions of the worker; that had really been the fundamental aspect of the work. Except during the immediate stress of the war, the endeavour had not been to increase output, but he could not recall a single instance in which improved conditions for the worker did not immediately result in economy; in other words, where the health and contentment of the worker were attended to, output and profits increased, and the neglect of the former necessitated to a great degree the decrease of the latter. An aspect of the subject which was well worth careful consideration was how far profits came to those whose ultimate object was profits, when they attended to that which had previously been thought to be a purely humanitarian aspect of labour. There was an old saying ascribed to an employer at the end of the eighteenth century, namely, that he gave his money to his employees and God gave it

in shovelfuls back to him. That aspect of the work of the Industrial Fatigue Research Board was an appeal to hard sound facts, and if it was grasped, as a result of what the author had said that evening, he thought it would be evident to everyone that the work of the Board must go on and must not be allowed to cease.

MISS E. B. VOYSEY (Welfare Workers' Institute) said she wished to support what Dr Collis had said and to say how much welfare workers appreciated the work of the Industrial Fatigue Research Board. It gave them ballast, so to speak. She was very often accused of being "up in the clouds" and having exaggerated notions about the value of welfare work, and she wished her critics had been present that evening, for they would then have realised that far from being visionaries, welfare workers had their feet resting on very solid facts and could claim that welfare provisions were very good business. People who urged the adoption of such provisions were often met with the remark: "Oh, but business is business." Generally those who said that meant that they were not going to have welfare work in their factories. She had recently been talking on the subject to a very obdurate employer, who said: "But you are away up in the clouds while we are digging down for profits." She had replied that he would not need to dig for profits if he took up the question of welfare work, because then the profits would flow in to him, and she wished he could have been present that evening to hear Mr Wilson's paper. She was particularly glad to hear the author say that he thought one of the greatest benefits of the work of the Board had been that it drew together employers and employed, made them understand the problems which confronted them both, and made them realise that their ultimate interests were identical, namely, the success of the undertaking. That was a fact which could not be emphasised too much. A great deal was heard nowadays about the need for co-operation, but it was important to go inside the factory and show what co-operation could mean in the very practical manner adopted by the Board. When that was done she thought much better results would be achieved. In conclusion, she wished to thank Mr Wilson and the Board in general for all they had done for the workers.

THE CHAIRMAN, in proposing that a hearty vote of thanks be accorded to Mr. Wilson for his paper, said he was very grateful to those who had spoken in appreciation of the paper, because it made his duty in conclusion very light and simple. There was only one point he would like to take the opportunity of emphasising. With reference to Mr. Pugh's remarks, it seemed to him personally that at the present time it would not be possible to do much good by making a kind of general

appeal to industry at large. With the limited funds at the disposal of the Board that course of action would be difficult, and he thought the activities of the Board for some time to come must be along the line of appealing to industry by industry, securing, as the author had indicated, the co-operation of the important industries in particular, and extending the work in that way until it was found that a fairly wide field had been covered and that the Board had something to offer the public in the way of substantial results. With reference to the question of publicity, he was strongly of opinion that the work of the Board should be made very widely known. Mr Parsons had referred to the characteristic ignorance of politicians with regard to such work. He certainly pleaded guilty at once to the indictment and almost pleaded guilty on behalf of the House as well, without injustice to his fellow Members of the House of Commons, because, when any economy campaign began, it seemed to make a bee line for the things which were most important in the welfare of the country and ignored other things which might quite well be done without. The remedy lay with the electorate of Great Britain. They were the cause, and the Members of the House of Commons were the more or less melancholy result! He wanted to emphasise the duty of the electorate as strongly as he could, because he believed it to be very important indeed. Personally he had not had a very long experience of the work of the Industrial Fatigue Research Board, but he could say that Mr Wilson had devoted a very great deal of time and energy to its progress. Those interested in the subject were very greatly indebted to him, particularly on the present occasion, because he had undertaken one form of the publicity enterprise in which they must all engage.

The resolution of thanks was carried unanimously.

MR D. R. WILSON, in reply, said he hoped the vote of thanks had not been given under any misapprehension, because, as he had explained, he could not personally claim any credit for any of the results he had shown. All that had been accomplished had been due to the energy and ability with which the staff of investigators employed by the Board had carried out their work, of which he could not speak too highly. He wished he had had time to explain the difficulties that had been experienced, not simply the financial difficulties but the difficulties of the actual investigations, as described in his written paper. He thought, however, that the audience would agree that the results he had shown on the screen reflected the greatest possible credit on the people who were actually responsible for them.

In reply to Mr. Parsons' remarks about

publicity, there was now in draft a full analysis of the work which the Board had carried out, which would probably be published in a few weeks and could be obtained from the Stationery Office in the ordinary way. That analysis would, of course, be very much more complete than the outline he had given that evening. He hoped every member of the audience who was interested in the subject would buy a copy. Certain reports of which he had given an outline in his paper, such as those on motion study and three or four others, would also be published shortly, and would, in fact, have been published nearly six months ago had it not been for the disorganisation in the work of the Board that had occurred at the beginning of the year. He hoped that when the full results of its past work were published it would be felt that the Board had thoroughly justified its existence.

The meeting then terminated.

NOTES ON BOOKS.

REPORTS ON THE PROGRESS OF APPLIED CHEMISTRY, issued by the Society of Chemical Industry, Vol V, 1920. Octavo, 625 pages. London: At the Office of the Society, Central House, Finsbury Square. Price 8s 3d to members; 15s. to non-members.

Perhaps the most difficult aspect of technical writing is the making of satisfactory abstracts of progress. Care will enable a writer to avoid any superfluous words, but the real and fundamental difficulty of the abstractor is to maintain a just balance of the relative importance of things so as to avoid too much use of subjects incidental to his own surroundings, companionships, and facilities or tastes in reading.

We must congratulate the editor, Mr T. F. Burton, on the abstracts and treatment, although in a few cases somewhat more rigid editorial control might have been exercised with advantage.

Seeking for a typical example of thoroughness and usefulness as an illustration to our readers of the real value of this epitome of progress, we selected the electrolytic zinc industry. Electrolytic zinc is virtually a new industrial metal, as it is free from the particles of more electro-negative metals which, in the case of ordinary zinc, set up electric strain, leading to corrosion. Hence pure electrolytic zinc does not dissolve like ordinary zinc in dilute sulphuric acid; indeed, it is scarcely acted upon by pure hydrochloric acid or pure sulphuric acid, whether strong or weak. The new zinc is easy to solder, and has manifold uses for electrical purposes and making the finer alloys. During some of the recent years it appears that between 30 and 40 thousand tons have been produced in the United States; moreover, at a

cost not much exceeding that of retort or furnace zinc.

Having prepared our technical notes or summary, from particulars given in the sequence of pages commencing with p. 281, we unexpectedly met with a nearly similar account (p. 255) of some of the operations, but with differences which cast a new light on the chemical aspect. It was impossible to avoid regret that it was apparently impracticable to unify both accounts or alternatively bring them into proximity. Cross-references between the two versions would have been a partial linking; but, at any rate, the p. 251 sequence might have been included in the index under the heading "Zinc, Electrolytic," or under "Electrolytic Zinc."

The electrolyte now used is a somewhat acid sulphate solution obtained by the action of sulphuric acid on the roasted ore-concentrates. The crux of the method, however, is the purification of the solution from metals which are electro-negative to zinc, such metals rendering effective electro-deposition impracticable by maculating the deposit which at a certain stage re-dissolves in the increasingly acid electrolyte by "local action," the maculated zinc acting like the copper zinc couple of Gladstone and Tribe. When the impurity of the electrolyte is considerable, no zinc is deposited, but hydrogen rises from the cathode at the beginning. Cobalt is notably subversive in the electrolyte solution, 15 parts per million inhibiting successful electrolysis. Some of the methods of purification are extremely ingenious. For example, if the iron content is below 0.3 gramme to the litre, it must be raised to this standard by the addition of an iron compound, after which the whole of the iron, together with some other metals, can be precipitated by lime. The electrodes are of aluminium for cathode and of lead for the anode. Hence the fluid becomes increasingly acid as the electrolysis proceeds, and the exhausted fluid can be resaturated with zinc.

The account of photographic materials and processes is of special value as being comprehensive and exact; indeed, this section is a distinct credit to the book, but there might have been fuller indications as to which details are new in relation to the year 1920. Thus, in reference to a suggestion made in 1920 as to the practicability of using potassium cyanide for the fixing of gelatine emulsions, there might have been a mention of the fact that in the early stages of gelatine emulsion work, cyanide was frequently used, and that on p. 253 of the 1912 edition of Cassell's Cyclopaedia of photography there is a comparison of the relative advantages of cyanide and "hypo." Similarly, in making mention of recognition during 1920 of the colour sensitising properties of potassium iodide there is no clear demarcation between what is new and what is old. Reference may be made to pp. 67, 68 and Fig. 28 of the 1851

edition of Hunt's Photography, as illustrating one of the early mentions of sensitiveness to the red rays brought about by the use of potassium or sodium iodide. There may be doubt as to whether the action in this particular case is due to colour sensitizing in an ordinary sense of the term, as the effect may be partly thermic, or of a secondary nature, as extinguishing, continuating, protective, or exciting, all more or less considered on p. 359 of the second edition of Hunt's *Researches on Light* (1854). *Researches and studies of this nature are often much complicated by the effects of minute traces of foreign matter in the materials.*

GENERAL NOTE

AIR TRAFFIC FROM PARIS.—The air traffic from Paris to England and other European countries has increased 300 per cent. since a year ago, according to the statistics published by the French Air Minister. During the month of May this year, 593 aeroplanes left the air port at Le Bourget with 1532 passengers, as compared with 297 machines and 519 passengers during the corresponding month last year.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock.

NOVEMBER 23.—**PROFESSOR JOHN AMBROSE FLEMING, M.A., D.Sc., F.R.S.**, Albert Medallist, "The Coming of Age of Long-Distance Wireless Telegraphy and some of its Scientific Problems" ("Trueman Wood" Lecture). **ALAN A. CAMPBELL SWINTON, F.R.S.**, Chairman of the Council will preside.

NOVEMBER 30.—**NOEL HEATON, B.Sc.**, "The Preservation of Stone." **SIR FRANK BAINES, C.B.E., M.V.O.**, Director of Works, H.M. Office of Works and Public Buildings, will preside.

DECEMBER 7.—**EMIL CAMMAERTS**, "Literature and International Relations." **H.E. the Belgian Ambassador** will preside.

DECEMBER 14.—**SIR WALTER BEAUPRE TOWNLEY, K.C.M.G.**, Minister to the Netherlands, 1917-19, "Trade with the Netherlands East Indies." **THE RIGHT HON. LORD EMMOTT, G.C.M.G., G.B.E.**, will preside.

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(Joint Meeting.)

At 4.0 p.m.

FRIDAY, NOVEMBER 25.—**A. H. ASHBOLT**, Agent-General for Tasmania, "An Imperial Airship Service." **BRIG.-GENERAL LORD MONTAGU OF BEAULIEU, K.C.I.E., C.S.I.**, will preside.

DOMINIONS AND COLONIES SECTION.

At 4.30 p.m.

TUESDAY, DECEMBER 6.—**FREDERICK COATE WADE, B.A., K.C.**, Agent-General for British Columbia, "British Columbia—The Awakening of the Pacific." **THE DUKE OF DEVONSHIRE, K.G., G.C.M.G., G.C.V.O.**, will preside.

Papers to be read after Christmas:—

LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

HOWARD MAURICE EDMUNDS, "Photo Sculpture."

CLOUDESLEY BRERETON, M.A., Divisional Inspector to the London County Council (Modern Languages), "Some Thoughts on Diction, and the Need of a National Conservatoire."

PHILIP SCHIDROWITZ, Ph.D., F.C.S., "Recent Developments in India Rubber Manufacture."

MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work."

JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "Electrical Driving in the Jute Industry."

W. A. APPLETON, C.B.E., Secretary to the General Federation of Trade Unions, "Economics and Labour."

EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "Some Solved and Unsolved Problems in Gas Works Chemistry."

ALEXANDER SCOTT, Sc.D., D.Sc., M.A., F.R.S., "The Restoration and Preservation of Objects at the British Museum."

ARTHUR WILCOCK, "Surface Printing by Rollers in the Cotton Industry."

GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

J. H. HUXLEY, "The Control of Sex in Animals."

J. T. MARTEN, I.C.S., M.A., "The Indian Census" (Indian Section).

ALEXANDER L. HOWARD, "The Timbers of India and Burma." (Indian Section.)

PROFESSOR WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S., "Brown Coals and Lignites: Their Importance to the Empire." (Joint Meeting, Dominions and Indian Sections.)

PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India" (Indian Section).

F. G. ROYAL DAWSON, M.Inst.C.E., Chief Engineer to Indian Railway Board, "The Need for an All-Indian Gauge Policy." (Indian Section.) SIR HENRY PARSALL BURT, K.C.I.E., C.B.E., will preside.

PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow of Magdalene College, Cambridge, *Sir George Birdwood Memorial Lecture*. (Indian Section.)

LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, G.B.E., K.C.M.G., "Queensland." (Dominions and Colonies Section.)
CANTOR LECTURES.

At 8 0 p.m.

MONDAYS.—ARTHUR M. HIND, O.B.E., M.A., Assistant-Keeper, Department of Prints and Drawings, British Museum, and Slade Professor of Fine Art in the University of Oxford, "Processes of Engraving and Etching." Three Lectures.

Syllabus.

LECTURE I.—NOVEMBER 28.—Wood-cut.—The Process and its Origin—The Early Anonymous Woodcutters—Original and Reproduction Work—Wood-cut and Wood-engraving—The great designers for Wood-cut: Dürer, Holbein and others—The special fitness of the Process for Book Illustration—Modern Work and its Scope.

LECTURE II.—DECEMBER 5.—Line-Engraving.—The Process and its Origin—Its Relation to the Work of the Goldsmith—The Great Masters of Original Engraving: Dürer, Marcantonio and others—Reproductive Engraving—Technical character of work in reference to the various aims of the Art.

LECTURE III.—DECEMBER 12.—Etching—The Process and its Origin—Survey of work by the great original Etchers: Rembrandt, Van Dyck and others—Examination of the special qualities of Etching in relation to different kinds of work—Recent Etching.

C. AINSWORTH MITCHELL, M.A., F.I.C. "Inks." Three Lectures. January 23rd, 30th, and February 6th.

ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., late Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington. "The Mechanical Design of Scientific Instruments." Three Lectures. February 20, 27, and March 6.

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, "The Constitutents of Essential Oils." Three Lectures. March 20, 27, April 3.

COBB LECTURES.

At 8.0 p.m.

MONDAYS, F. F. RENWICK, F.I.C., F.C.S., A.C.G.I., "Modern Aspects of Photography." Three Lectures. May 1, 8, 15.

MANN JUVENILE LECTURES.

At 3.0 p.m.

WEDNESDAYS, JANUARY 4 and 11, 1922, WILLIAM REGINALD ORMANDY, D.Sc., "Clay: What it is—Where it comes from—and What can be done with it."

MEETINGS OF SOCIETIES FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 21.. Cold Storage and Ice Association, at the Royal Society of Arts, John Street, Adelphi, W.C., 5.30 p.m. Presidential address by Mr. G. Goodair.

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal Meeting.) Mr. A. J. Hainsworth, "Hydro-Electric Power."

Geographical Society, 135, New Bond Street, W., 8.30 p.m.

British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. G. H. Widdows, "School Design."

East India Association, 7, Tothill Street, Westminster, S.W., 3.30 p.m. Rev. Oswald Younghusband, "The English Boy in India."

TUESDAY NOVEMBER 22.. Sociological Society at the Royal Society, Burlington House, 8.15 p.m.

Mr. G. Russell, "The Causes of the Conflict between Great Britain and Ireland."

WEDNESDAY, NOVEMBER 23.. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 4.30 p.m.

"Trueman Wood" Lecture. Prof. J. A. Fleming, "The Coming of Age of Long-Distance Wireless Telegraphy and some of its Scientific Problems."

Geological Society, Burlington House, W., 5.30 p.m.

Electrical Engineers, Institution of (South Midland Centre), The University of Birmingham, 7 p.m. Mr. W. Wilson, "Some Notes on the Design of Liquid Rheostats."

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5 p.m.

THURSDAY, NOVEMBER 24.. University of London, at the Imperial College of Science, South Kensington, S.W., 5.30 p.m. Mr. W. Bateson, "Recent Advances in Genetics." (Lecture IV.)

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., 6 p.m. Mr. C. Hay-Murray, "Phrenology as an aid to Education."

Camera Club, 17, John Street, Adelphi, W.C., 8.15 p.m. Miss Olive Eddis, "A Colour Photography Trip in Canada."

Optical Society, at the Imperial College of Science and Technology, South Kensington, S.W., 8 p.m. Prof. P. J. Cheshire, "The Polaroscope from a Historical Standpoint."

Mechanical Engineers, Institution of (N.-Western Branch), Memorial Hall, Albert Square, Manchester, 7 p.m. Dr. E. H. Salmon, "The Machinery of Floating Docks."

(Midland Branch), The University, Birmingham, 7 p.m. Mr. T. A. Pain, "The Equipment of a Modern Boiler House."

Chromatics, International College of, Caxton Hall, Westminster, S.W., 8 p.m. Dr. A. C. Crommelin, "Colour and the Stars."

FRIDAY, NOVEMBER 25.. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 4 p.m. Dominions and Colonies and Indian Sections (Joint Meeting). Mr. A. H. Ashbolt, "An Imperial Airship Service."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Journal of the Royal Society of Arts.

No. 3,601.

VOL. LXX.

FRIDAY, NOVEMBER 25, 1921

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, NOVEMBER 28th, at 8 p.m.
(Cantor Lecture.) ARTHUR M. HIND,
O.B.E., M.A., Assistant-Keeper, Department of Prints and Drawings, British Museum, and Slade Professor of Fine Art in the University of Oxford, "Processes of Engraving and Etching." (Lecture I.)

WEDNESDAY, NOVEMBER 30th, at 4.30 p.m.
(Ordinary Meeting.) NOEL HEATON, B.Sc.,
"The Preservation of Stone." SIR FRANK BAINES, C.B.E., M.V.O., Director of Works, H.M. Office of Works and Public Buildings, will preside.

NOTE.—The attention of Fellows is drawn to the fact that the hour of this meeting has been changed from 8 p.m. to 4.30 p.m.

THIRD ORDINARY MEETING.

WEDNESDAY, NOVEMBER 16th, 1921; Mr. BASIL OLIVER, F.R.I.B.A., in the chair.

The following candidates were proposed for election as Fellows of the Society :

Blagg, Percy, London
Elton-Bott, John Richard, Burma
Ross, Alexander G., Fiji
Sanders, Marion Eugénie, London
Wright, Hugh Francis, New Barnet, Herts

The candidates proposed at the opening meeting on November 2nd, of whom a list was published in the *Journal* of November 11th (pages 847-8), were duly elected Fellows of the Society.

A paper on "Modern Buildings in Cambridge, and their Architecture," was read by Mr. T. H. Lyon, M.A., Director of Design in the University School of Architecture, Cambridge.

The paper and discussion will be published in the *Journal* of December 2nd.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

WEDNESDAY, NOVEMBER 2nd, 1921.

MR ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, in the Chair.

THE CHAIRMAN, in opening the meeting, said it was the Inaugural Meeting of the 168th Session of the Society, and the Council had done him the very signal honour of electing him as Chairman of the Council for a fourth time. He believed that in the history of the Society only five previous Chairmen had been re-elected for a fourth time, viz., Mr. William Hawes, Sir Thomas Phillips, Lord Henry Gordon Lennox, Lord Alfred Spencer Churchill, and Sir Richard Webster (afterwards Lord Alverstone), and he wished to express to the Society and also to the Council his very high appreciation of the honour that they had done him.

His first business as Chairman was to present the Society's Medals to a number of eminent persons who had read papers before the Society. The recipients of the Medal on the present occasion were so very eminent that he could not help thinking that, in giving Medals to those distinguished persons, the Society was really not honouring them but honouring itself. At any rate, it was making the Medal of the Royal Society of Arts a very high distinction.

THE CHAIRMAN then presented the Medals to the following :

To those who have delivered the Trueman Wood Lecture.—

SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., "Discovery and Invention" (1917).

SIR HERBERT JACKSON, K.B.E., F.R.S., "Glass and some of its Problems" (1919).

SIR OLIVER LODGE, D.Sc., Sc.D., LL.D., F.R.S., "Sources of Power known and unknown" (1919).

SIR DANIEL HALL, K.C.B., F.R.S., "The Present Position of Research in Agriculture" (1920).

For the Sir George Birdwood Memorial Lecture:—

LIEUT.-COLONEL SIR EDWARD W. M. GRIGG, K.C.V.O., C.M.G., D.S.O., M.C., "The Common Service of the British and Indian Peoples to the World."

For Papers read at the Ordinary Meetings:—

MAJOR-GENERAL THE RIGHT HON. LORD LOVAT, K.T., K.C.M.G., K.C.V.O., C.B., D.S.O., "Forestry."

COLONEL ROBERT J. STORDY, C.B.E., D.S.O., "The Breeding of Sheep, Llamas, and Alpacas in Peru, with a view to supplying improved Raw Material to the Textile Trades."

ANDREW FRANCIS BAILLIE, Chief Engineer, Technical Department, Anglo-Mexican Petroleum Company, "Oil Burning Methods in various Parts of the World."

WILLIAM CRAMP, D.Sc., M.I.E.E., "Pneumatic Elevators in Theory and Practice."

SIR KENNETH WELDON GOADBY, K.B.E., M.R.C.S., D.P.H., "Immunity and Industrial Disease."

For Papers read in the Indian Section:—

WILLIAM RAITT, F.C.S., Cellulose Expert to the Government of India, "Paper-pulp Supplies from India."

THE HON. SIR GEORGE SEYMOUR CURTIS, K.C.S.I., "The Development of Bombay."

For a Paper read in the Colonial Section:—

A. H. ASHBOLT, Agent-General for Tasmania, "Industrial Development in Australia during and after the War."

For a Paper read at a Joint Meeting of the Indian and Colonial Sections:—

SIR CHARLES H. BEDFORD, LL.D., D.Sc., late Chemical Examiner to the Government of India, "Industrial (including Power) Alcohol."

THE CHAIRMAN said that at the opening of the previous Session the Society was in a somewhat precarious position. Perhaps all the members of the Society were not so well aware of that fact as were the members of the Council. The House of the Society was erected for it by the brothers Adam some 150 years ago, upon the prevailing custom of a 99 years' lease, and the lease had long ago expired. It had been renewed from time to time by the proprietor, Mr. Drummond, but finally the Society had got down to a two years

tenure, and at the beginning of last year it received an intimation that it must either pay a very much higher rent, a rent that it could hardly afford to pay, or buy the freehold. He need scarcely mention the fact that neither the previous nor the present year was a very suitable time for raising money, and the members of the Council were rather perturbed as to the outlook. They started a subscription list among their friends and promises were obtained of something like £10,000, but that was only a small amount compared with the value of the premises. However, during the year, thanks entirely to Mr. Menzies, the Secretary, the Society had had the good fortune to meet with a munificent benefactor who desired to remain anonymous, and who had paid into the Society's banking account the large sum of £30,000. With that sum and with the other sums already promised and, of course, one could always borrow money upon a freehold the Society was in a position to buy the building. But, as the members knew, a general appeal had just been issued to them for further subscriptions. It was desired not only to buy the freehold of the historic house, but also to add something to its amenities. The Council did not want to destroy a certain quaintness that there was about the rooms at the present time, for the Society had been occupying those rooms for more than 150 years, but wished to make various improvements. The lecture hall required painting, the library needed renovating, a smoking room and a cloak room should be provided, and so forth. The Council was, therefore, anxious to enlist the sympathy of the members of the Society to produce a certain amount of money besides that which had already been given. The appeal was only sent out on the previous day, but a gratifying number of responses had already been received. It must be understood that a Society such as the Royal Society of Arts was very much affected by the increased cost of things in general and more especially of printing. The cost of the Society's *Journal*, which was published weekly, was in 1913/1914 £1,767, and in 1920 that sum had increased to £4,541, although the number of pages in the *Journal* was reduced from 1,050 to 840. By printing the *Journal* in the country during the present year, however, there would be a considerable saving. From January to August, 1921,

it cost £2,477 as against £2,814 in the corresponding months of 1920, a reduction of £337. That reduction would have been £600 had not the postage been increased from a half-penny to a penny. It was probable that the cost of production would diminish slightly. Already the printers had agreed to a reduction of 5 per cent., and a further reduction of 5 per cent. later had been promised. He mentioned those figures to show the difficulties of such a Society at the present time. As the members knew, the subscription had been increased, and that had had a gratifying result. It was realised that the increase of the subscription would probably bring about a certain number of resignations. An increase of subscription invariably had that effect, not only in the case of Societies such as the Royal Society of Arts, but in the case of clubs and other bodies. The result of the increase was as follows: From January 1st to October 31st, 1920, the subscriptions amounted to £4,454, and for the same period in 1921, they amounted to £5,561, or an increase of over £1,000. It was, therefore, clear that the policy of increasing the subscription from two guineas to three guineas per annum was going to increase the revenues of the Society, although it had unfortunately brought about a certain number of resignations. It was now for the members of the Society to induce their friends to join in order to make up the loss in numbers that had been sustained. The loss was only 260 out of a total of 3,200, so that he thought a little propaganda on the part of the members would bring the membership back to its former level.

As the present meeting was the first that had taken place since the Society received the munificent anonymous gift of £30,000 to which he had referred, he wished to propose that the following resolution should be passed:—

“That this Society, at the opening meeting of their 168th Session, do instruct the Secretary to convey their most grateful thanks to the anonymous benefactor who, by his munificent gift of £30,000, will enable them to complete the purchase of the historic house which was built for them by the brothers Adam and which they have occupied for over a century and a half, and has also enabled them to carry on with unabated vigour their work for the encouragement of arts, manufactures and commerce, in which

they have been continually engaged since 1754.”

If the meeting would pass that resolution, the Secretary, who knew the name of the donor, would convey the resolution to him.

The resolution was carried with acclamation.

THE CHAIRMAN then delivered the following address:—

WIRELESS TELEGRAPHY.

AN ADDRESS

Delivered at the opening meeting of the 168th Session of the Royal Society of Arts on the 2nd November, 1921.

By ALAN A. CAMPBELL SWINTON,
F.R.S., M.Inst.C.E., M.I.E.E., M.I.Mech.E.,
Chairman of the Council of the Society.

The subject of wireless telegraphy appeals so much to everybody at the present time, that I do not know that I need apologize for giving you an address on that subject. I chose the same subject for my address last year, but it is of perennial interest. Furthermore, if I again go over a certain amount of old ground, I hope that in doing so I shall be able further to elucidate points that, so far, at any rate to the man in the street, are not altogether plain.

As I have previously shown in this room, for the reception of messages from the more powerful wireless stations, it is not necessary to employ an external aerial, all that is required being a comparatively small coil of wires called a frame or loop aerial, such as is illustrated in Fig. 1. As is well known, a frame of this description has directional properties; that is to say, it receives best when the plane of the frame is set in the direction from or to which the wireless waves are travelling. When the plane of the frame is set at right angles to the direction of the waves, then reception ceases. This minimum position, when signals cease to be heard in the telephones, is more sharply defined than the maximum position when the signals are loudest; so, to find the direction of the sending station, the practice is to employ the minimum position of the frame when one knows that the direction of the station is exactly at right angles to this position.

The explanation that is usually given of the working of a frame aerial of this kind is, that when the waves strike

FIG. 1. FRAME AERIAL.

the wires on the near side of the frame they are in a slightly different condition of phase than they are when they strike the wires on the further side of the frame. To take an extreme case, if the distance between the two sides of the frame were equal to one-half a wave length,

then it is clear that the waves, when they strike the wires on the near side of the frame would be exactly in opposite phase to what they would be when they strike the wires on the further side. Of course, as a rule, the frame is very much smaller than half a wave length in size. For instance this frame is only 1 metre across, whereas the waves from the Eiffel Tower are 2,600 metres in length, and half a wave length would be 1,300 metres. The difference in phase, therefore, on the two sides of a frame such as is shown is very small, but still, it is sufficient to cause oscillatory electric currents to travel round and round the wires of the frame corresponding to the wave frequency.

Mr. R. C. Clinker, of Rugby, has kindly lent me a very pretty model illustrating the action of a frame, a photograph of which model is shown in Fig. 2.

The model consists of a horizontal sliding wood piece having a sinuous upper edge which operates upon two vertical sliders carrying arrow heads, which can be set at different distances apart. The horizontal motion represents the passage of an electric wave across the vertical sides of a rectangular coil, and the vertical motions of the arrows show the amplitudes and phases of the electro-motive forces induced in the sides of the coil. The resultant E.M.F. available at any instant is the vertical distance between the arrow tips as shown on the scale. With the sliders set close

FIG. 2. MODEL TO ILLUSTRATE WORKING OF FRAME AERIAL.

together, this distance is small compared with the total distance moved by each slider. With the sliders set further apart this distance becomes larger, until, with the sliders at a half wave length apart, the maximum is obtained. This illustrates the fact that the useful E.M.F. of a frame aerial is only an exceedingly small difference between two large quantities, as the width of the frame is generally a very small fraction of the wave length. If, in the model, the two sliders are placed at the same point of the wave (for which double rollers are provided), the same vertical motion is obtained as before, but there is no distance between the tips, i.e., no useful E.M.F. is produced. This represents the case where the receiving frame is turned so that its plane lies at right-angles to the direction of the wave travel, when no signals are obtained.

As mentioned, it is by taking into account the difference in phase on the two sides of the frame that its working is usually explained; but some months ago Sir Oliver Lodge gave me an explanation which I think in some ways is more easy to understand. The waves sent out by wireless stations are electromagnetic waves, which consist of two components, one electric and the other magnetic. The electric component is vertical to the ground from which it follows that the magnetic component is horizontal. When, therefore, the frame is turned so that its plane is in the direction of the travel of the waves, the magnetic component passes backwards and forwards through the interior of the frame. This has just the same effect as if you thrust a magnet in and out of a coil of wire, which, as you know, causes a current of electricity to pass in the coil first in one direction and then in the other, as the magnet advances or recedes. Similarly, as these magnetic pulses oscillate backwards and forwards through the coil of which the frame aerial consists, electric currents are caused to oscillate backwards and forwards through the coil with the same frequency as the oscillations of these magnetic pulses.

In some ways, perhaps, this is a simpler explanation than the one usually given; it is based on the idea that it is the magnetic component of electromagnetic waves which is chiefly active in operating a frame aerial, just as it is probably chiefly the electric component which operates a tall external aerial reaching up into the sky.

In the particular frame aerial shown in Fig. 1, there are altogether 100 turns of wire spaced so that the various turns are not in contact, the spacing being for the purpose of reducing the electrostatic capacity between the turns. Arrangements are made, further, by means of plug connections, whereby either the whole 100 turns can be employed, such as are required for receiving very long waves up to 20,000 meters, or a lesser number of turns, say 50, 35, or 15, can be used. For a medium wave station such as the Eiffel Tower, whose wave length is 2,600 metres, either the 35 turns or 50 turns will suffice, the only difference being that when 35 turns are used the tuning condenser, which is connected across the ends of the coil, has to be adjusted to give a rather larger capacity than when 50 turns are employed, when the tuning capacity has to be reduced almost to nothing.

As will be observed in the frame aerial illustrated, the turns of wire are arranged in two sets of 50 turns each, each 50 turns being wound radially so that each succeeding turn is outside the one before it. This is one way of winding these frames; but another way is to wind all the turns side by side so as to form a cylindrical spiral, all the turns being parallel and of the same diameter. The two methods of winding do not appear to differ very much so far as practical results are concerned, but theoretically, at any rate, the radial form of winding should give the sharpest position of silence which indicates that the plane of the frame is at right angles to the direction from which the waves are coming, whereas the parallel form of winding should give the most sharply defined position of maximum strength of signals such as is obtained when the plane of the coil corresponds with the exact direction of the waves, this for the reason that, with the parallel form of winding when the plane of the frame corresponds with the direction of the waves, the latter will reach all the wires at one side of the frame at the same instant, whereas with the radially-wound frame, this occurs when the plane of the frame is at right angles to the direction of the waves.

In either case, of course, the frame aerial merely indicates the general direction of the waves, but leaves undetermined the absolute direction, that is to say, it will not tell you whether the sending station is to the north or south, but merely that it is, in one or other of these directions.

In order to arrive at a method of finding the absolute direction, I recently carried out a series of experiments in which the frame, which was a small one only one foot in diameter, but with which signals from the Eiffel Tower, Paris, were easily received, was placed in a copper box in the form of a cube two feet dimensions in each direction, made of sheet copper about $\frac{1}{2}$ inch. in thickness. This box was completely closed in with soldered joints, excepting on one side, which was open, but could be closed by means of a close-fitting lid also made of similar sheet copper. In all the experiments, the copper box was connected to earth.

Preliminary experiments, in which only the frame aerial was enclosed in the copper box—the amplifier, tuning condenser, telephone receiver, and batteries being outside—having proved unreliable owing, apparently, to the outside apparatus picking up the waves irrespective of the frame, it was decided to put the whole of the apparatus and connections, as well as the frame, inside the box, and to listen to the telephone receiver through a $\frac{1}{2}$ -inch rubber tube passed into the box through a round hole in the latter. Considerable trouble was experienced in getting the apparatus to work properly under these conditions, the close proximity of the frame and the amplifier causing reactions that were apt to lead to automatic howling, but with care, clear signals were obtained.

Experiments were made with the 2600-metre spark emission from the Eiffel Tower.

Though putting the frame and other apparatus into the box greatly reduced the strength of the received signals, still, when the frame was pointed in the right direction, with the open side of the copper box turned towards Paris, the signals could be heard quite easily. They were probably only about five per cent. of the strength obtained with the frame completely unshielded.

On closing up the open side of the box with the copper lid, it was found that as the lid was put on, the signals further gradually diminished in strength. They were, however, still distinctly audible so long as the narrowest possible slit or opening was left. Indeed, they only disappeared, and did so quite suddenly, when the edges of the lid came into actual contact with the box so as to form a closed continuous electrical conductor round the frame. With

the lid quite closed, and making good electrical contact all round, no trace of the signals could be heard.

Experiments were also tried with a lid consisting of thin tin-foil pasted on wood, in place of the copper lid. This lid was just as effective as the copper one in stopping the signals. When the tin-foil lid completely closed the aperture and made good contact all round with the copper box, no trace of any signals could be obtained.

As mentioned, all these results were obtained with the open side of the box facing Paris, but exactly similar results, with no distinguishable difference as regards the strength of the received signals, were obtained when the box was turned round so that its open side was pointing in the exactly opposite direction from Paris. By such means it is therefore not possible to ascertain the absolute direction of the waves any better than with an unshielded frame.

With the box turned so that its open side pointed in a direction at right angles to the direction of Paris, either to the right or to the left, but with the frame pointing in the direction of Paris, no signals at all could be heard, though the side of the box was completely open; but with the box so placed that its open side pointed in a direction making an angle of 45 degrees with the direction of Paris, with the frame pointing in the same direction or more towards Paris, the signals could be heard, though faintly, being reduced to some 1 per cent. of their value with the frame completely unshielded.

For any signals to be heard, it was, however, essential that the relative positions of the box and frame were such that a prolongation of the plane of the frame towards or away from Paris, no matter which, came out of the open side of the box, clear of the copper sides.

With the box turned up so that its open side pointed to the sky, with the vertical frame pointing to Paris, the signals could be heard at about 1 per cent. of their full unshielded value, and disappeared when the lid was put on, in exactly the same way as when the open side of the box was pointing to, or directly away from Paris.

From these experiments it would appear that waves of the length and strength of those experimented with do not penetrate into a completely closed metallic box to a sufficient extent to give audible signals

with a frame aerial and amplifier of the description used, even if the side of the box facing the source of the waves is only closed with tin foil. Further, it would seem that the screening effect is largely a matter of a closed electrical conducting circuit in that portion of the box that surrounds the periphery of the frame, the smallest break in the electrical conducting continuity interfering largely with the screening effect.

That this is so, is shown by further experiments made with a flat sheet of tin plate, 5 feet in length and 8 inches wide, bent so as to form a cylinder. This was placed over the frame so that the axis of the cylinder coincided with that of the frame. With the ends of the tin plate

but only a damping effect, which also greatly diminished the strength of the signals.

The result obtained with the frame inside the copper box, in getting signals of equal strength with the open side of the box facing away from the source of the waves, as when the open side faced towards such source, may, perhaps, be of some interest from the point of view of theory, in throwing some light upon the mechanism of electro magnetic wave phenomena.

Though these results are of value, as you see, they do not solve the problem of enabling the frame to indicate the absolute direction. However, this can be done by employing, in conjunction with the frame, an ordinary small external aerial. Fig 3

FIG 3 UNITED STATES NAVY WIRELESS COMPASS

sheet overlapping, but not in electrical contact, the effect in reducing the strength of the signals was small, but immediately increased considerably, so that the signals were reduced to about 20 per cent of their original strength, when the ends of the sheet were allowed to touch so as to form a continuous conducting ring round the periphery of the frame. Contracting the diameter of the ring by sliding the overlapping ends of the plate so that the ring was closer to the frame all round, still further reduced the strength of the signals, till when the ring was touching the insulated wires of the frame all round, the signals very nearly disappeared. This indicates that the effect is not merely a question of screening, but also of eddy current damping, which was further shown by contracting the tin plate cylinder still further, and placing it inside the frame, where it again had the effect of largely reducing the strength of the signals. That damping enters largely into the matter was also proved by placing a large flat copper plate close up to one side of the frame, where it could have no screening

shows the connections in this arrangement, which goes by the name of the United States Navy Wireless Compass. In the illustration, A1 is the external aerial, A2 the frame aerial, L1 and L2 is the usual loose coupled tuner, while L3 is an inductance which is made of exactly the same value as the inductance of the frame. C1 is the usual tuning condenser, while V is the valve connected with the telephone T and the battery B. In practice, of course except for very loud and near stations several valves would be employed to produce the necessary amplification.

As will be seen, by means of the switch S, either the frame A2 or the inductance L3 can be connected in series with the secondary (L2) of the loose coupled tuner. When the switch is turned to the right the frame is short circuited, and the signals received are those coming from the external aerial A1. When the switch is turned to the left, the frame aerial A2 is put in series with L2, so that the signals received are the combined result of what is caught by the external aerial and the frame. Bv means

of the loose coupling of the tuner, the strength of the signals received from the two aërials can be balanced until they are about equal. Then, if the frame is turned in one direction, the signals that are caught by the frame reinforce those that are caught by the external aerial; whereas, if the frame be now turned through 180 degrees so as to point exactly the opposite way, the signals caught by the frame interfere with those caught by the external aerial. In this way, with the frame pointing in one direction very much louder signals are obtained than when the frame is pointing in the opposite direction, and the apparatus having been calibrated upon a station the absolute direction of which is known, it will serve to tell the absolute direction of other stations. The reason for inserting the inductance L3, which has the same inductance as that of the frame, is so as not to interfere with the tuning when the switch S is turned one way or the other. Much sharper direction finding can be obtained with the frame alone; so in practice, with this apparatus, fine readings of the direction are taken with the frame alone, and readings for the absolute direction with the two aërials used conjointly.

I must now explain to you some more of the apparatus with which we are going to show experiments this evening, and, first of all, I will begin with the six-valve amplifier, the front appearance of which is shown in Fig. 5, while the back is shown in Fig. 6; Fig. 4 being a diagram of the connections.

In my address last year, as you may remember, I described a seven-valve amplifier of the resistance type. The amplifier which I am showing this evening is not a resistance amplifier, but is what is called a transformer amplifier, connection from the plate of one valve to the grid of the next valve being by means of small transformers.

The production of an amplifier that will respond equally well to all wave lengths, from the 180-metre wave length imposed by the authorities for many amateur stations up to the 20,000-metre wave lengths, and more, in use in several of the Continental and American stations, is a matter of considerable interest to all scientific investigators.

In many commercial stations, as, for instance, in those on board ship, as a rule only a very limited range of wave lengths is dealt with, so that the usual design of amplifier can be made to give effective results over the whole range that is required.

In the larger receiving stations, moreover, there is no difficulty in providing several separate amplifiers suited for a number of particular wave lengths. When, however, we come to the ordinary experimenter, this individual usually wishes to be able to receive efficiently both the shortest and the longest wave lengths that are emitted, while, at the same time, by reason of the expense, and also owing to the exigencies of space, in this case a number of separate amplifiers are usually out of the question. Thus probably only one amplifier is provided, and this is usually only really efficient for waves of medium length, giving inferior results, both with very short waves and with very long ones.

The so-called resistance form of amplifier, in which succeeding valves are connected together by small condensers, is probably the form of instrument that, without alteration or adjustment, will give the greatest range as regards wave lengths. Unfortunately, however, resistance amplifiers do not appear to be at all suitable for short waves; indeed, they only begin to become effective with wave lengths of about 1,000 metres. Again, even for long waves, resistance amplifiers appear to require more valves than do transformer amplifiers in order to get the same result, in the proportion of seven or eight as against six.

No doubt transformer amplifiers can be made to operate with a wide range of wave lengths by employing transformers with tappings on the primary, and perhaps best also on the secondary circuits, so that the number of primary and secondary turns in use can be varied at will. Such arrangements, however, require complicated switching devices which, unless very skilfully constructed, are very apt to give trouble, while there is the objection that the electrostatic capacity of the unused turns is apt to cause a certain loss in efficiency.

A very simple solution of the problem has been recently suggested. Mr. H. H. T. Burbury has had the happy idea of constructing a six-stage amplifier in which the first three transformers, which are of the air-core variety suitable for radio-frequency, are made readily removable, each being fitted with four pins connected to the ends of the primary and secondary circuits, exactly similar to the pins at the base of the "R" valve, while "R" valve sockets of the usual construction are employed for the transformers to fit into.

A number of different sets of transformers, wound with different numbers of turns to suit different wave lengths, can thus be used; while to bridge over the difference between one set of transformers, each with a particular number of turns, and the next set, each with a larger number of turns, and thus obtain proper resonance, adjustable condensers are employed across the primaries of the transformers. In this way, with a sufficient number of interchangeable transformers, the best possible results can be obtained on a single instrument with any wave length.

The amplifier which is shown is constructed on this principle.

The instrument is, as you will see, a six-stage amplifier, the first three valves being operated at radio-frequency, while the fourth is a detector valve supplied through a leaky condenser, the last two valves operating at audio-frequency.

Each of the first three air-core radio-frequency transformers consists simply of a flat circular disc or bobbin of ebonite, with a groove round the periphery in which the

the primary and secondary in separate grooves, or in the same groove, employing two separate coils the distance between which could be varied so as to change the amount of coupling. He found that, in spite of what the text books say, the tighter the coupling the better, and so now prefers to wind his primary and secondary together in the same groove. When this is done, however, it is necessary to give careful attention to the insulation of the wires, as otherwise a short circuit may prove disastrous.

For receiving 300-metre waves, 50 turns for both primary and secondary will be found sufficient, while 100 turns give good results for 600-metre waves. For longer waves, say, of 1,000 metres and upwards, we have transformers in which primary and secondary have each 250, 400, 650, 1,000 and 2,500 turns, the latter being suitable for receiving Carnarvon, Lyons and Lafayette, near Bordeaux, the last having, it is understood, a wave length of 23,450 metres.

A complete diagram of the connections

FIG 4 UNIVERSAL AMPLIFIER; CONNECTIONS

primary and secondary coils are wound. In most cases the primary and secondary are wound simultaneously off two spools in the same groove, the primary and secondary having an equal number of turns; but in other cases the primary and secondary have been wound in two separate grooves close together.

In connection with this point it may be of interest to mention that Mr. Burbury has tested the relative advantages of winding

of the six-valve amplifier is shown in Fig. 6 in which V_1 V_2 V_3 are the three valves working at radio-frequency. V_4 is the detector valve, and V_5 and V_6 valves work at audio-frequency.

T_1 T_2 T_3 are the three removable radio frequency transformers, while T_4 and T_5 are fixed audio-frequency transformers, iron-cased and with iron cores, with step-up transformation of 1 to 5.

The adjustable tuning condensers (C_2

FIG. 5. UNIVERSAL AMPLIFIER; FRONT VIEW

C_3 and C_1 are connected across the primary windings of the radio-frequency transformers. By means of a toothed rack and gear wheels, they are all connected together, so that one adjustment alters all three condensers simultaneously.

The leaky condenser, C_5 is employed to produce detection in valve V_4 .

A small condenser, C_6 , is used to by-pass, for high-frequency currents, the primary of the audio-frequency transformer, T_1 . The usual condensers, C_7 and C_9 , are also connected across the high-tension battery and the telephones. A potentiometer is employed to control the grid voltage of valves V_2 , V_3 and V_1 , while the two audio-frequency valves and the detector valve have separate rheostatic controls to their filaments from the three other valves.

The instrument is arranged so that either magnetic or electrostatic reaction can be employed. As shown, the magnetic reaction is obtained by means of a coil connected between the plate of the fourth valve and the primary of the transformer, T_4 . A switch is used to short-circuit this reaction coil when not in use. Provision is also made for electrostatic reaction between the plate of either the second or fourth valve and the grid of the first valve through a small adjustable condenser, C_3 .

For the reception of C.W. signals, either the magnetic or the electrostatic reaction can be used to make the instrument self-heterodyning, or a separate heterodyne can be employed.

Fig. 5 shows the appearance of the front of the instrument. The input terminals, as also those for connecting the magnetic reaction coil, are on the left, while all the other terminals are on the right. The three removable radio-frequency transformers, with their connection pins, will be observed at the top on the left. The potentiometer is on the centre of the upright part of the instrument, with the filament-control rheostats on each side of it, while below are the three tuning condensers for the radio-frequency transformers and the adjustable condenser for capacity reaction. In the centre, below the potentiometer, is a three-way switch for connecting the capacity reaction condenser to the plate of the second or fourth valve, or for disconnecting it.

Fig. 6 shows the back view of the instrument, with the three radio-frequency transformers on the right, at the top, and the two audio-frequency transformers on the left. The leaky condenser and its leak are at the bottom, and the by-pass condenser, C_6 , and the telephone condenser, C_9 , at the top, on the left. The back of the valve sockets and of the potentiometer, and one filament rheostat, are also visible.

As loud-speaking telephones to make Morse signals, speech and music audible throughout the room, we have both one of Mr. Sidney Brown's well-known reed instruments, fitted with a specially large trumpet, and with a special diaphragm, and also an example of the American

FIG. 6. UNIVERSAL AMPLIFIER ; BACK VIEW.

instrument known as the Magnavox. This latter instrument differs from ordinary telephone receivers inasmuch as the vibrations of the diaphragm are caused by the varying electric currents passing in a circular coil of wire attached to the diaphragm, which coil is placed in a very powerful magnetic field produced by a battery current through an electro-magnet. The two poles of this electro-magnet are concentric one inside the other, leaving between them an annular space in which the coil is free to vibrate and across which the magnetic field is radial. So long as there is no current flowing through the coil, there is no initial pull on the diaphragm, as there is in ordinary magnetic telephones, so that it is claimed the diaphragm is more free to move in exact accordance with the wave form of the actuating electric current.

On the occasion of a recent trip to Paris, I visited, at Levallois Perret, the receiving station of the Société Française Radio-Electrique, where long-wave messages and signals from Annapolis, near New York, and other American stations are photographically recorded. The signals are received on a large frame aerial some three metres in diameter, mounted inside the loft of a three-storey building, the amplifiers and other receiving instruments being on the ground floor immediately below the frame aerial. All the receiving instruments are contained, in a windowless copper room ;

that is to say, a room large enough to contain the instruments and operators, which is covered all over, top, sides and even the door, with sheet copper connected to earth. This arrangement is employed to shield the instruments from disturbances, the station being situated in the middle of works where many electrical experiments are constantly being made. The frame aerial, which is of cylindrical form, is connected to the amplifiers through a step-up high frequency transformer, the primary consisting of a few thick turns, and the secondary of many turns of smaller wire. There is nothing very special about the amplifier, which is of the transformer type, excepting that the transformers, though used for high frequency currents, have iron cores, the iron being of special quality and very finely divided. Furthermore, the transformers are shielded from outside influence and from one another by being separately enclosed each in a sheet-iron box. After being amplified, the signals are very clear and loud ; indeed, an American station near Panama which was sending on the occasion of my visit, could be heard all over the room. For the purpose of getting rid of atmospheric disturbances which, on these long-distance transmissions are apt to have particularly baneful effects, what is known in America as an "x-stopper" is employed. This is an instrument in which the plate currents from the amplifier are caused to pass through two circuits,

FIG. 7. PARIS OSCILLOGRAPH RECORD OF AMERICAN STATION

so arranged that, by acting on one another they reduce the sounds due to atmospherics to a greater extent than they reduce the sound of the signals. This they do by taking advantage of the fact that, whereas the signal waves are tuned to some definite wave length, the waves due to atmospherics are untuned, and have no definite wave length. As a result, though the strength of signals is also somewhat reduced, the disturbances due to atmospherics are almost entirely eliminated. For finally recording the signals an oscillograph of the Blondel, or Duddell type is employed. This consists of a narrow strip of phosphor bronze stretched to the requisite tension to make it respond readily to the audio-frequency of the electric currents from the amplifier, which are passed through it after being transformed by a step-down transformer, which reduces their voltage and increases their amperage. The phosphor bronze strip is mounted in a very intense magnetic field which causes it to assume rapid vibration when furnished with current of the appropriate frequency. On the centre of the strip is mounted a small mirror from which a narrow pencil of intense light from an arc lamp is reflected on to a moving band of photographic paper. When the strip and mirror are at rest, the pencil of light is focussed to a point on the centre of the paper band, and as the latter moves, it draws a straight line along the centre of the band. When, however, the strip and mirror are put into vibration, the spot of light vibrates across the paper band at

right angles to its length, on both sides of the central line. The vibrations are too rapid relatively to the speed of the paper band to show individually, the result being to give on the developed paper the effect of a number of elongated beads upon the central line, a short bead representing a dot and a long bead a dash of the Morse alphabet. Fig. 7 shows a reproduction of some of the records obtained with this instrument in my presence. The machine is self-acting, the photographic paper, after having been exposed to the vibrating spot of light, passing automatically successively through developing, fixing and washing baths. The chief advantage of the arrangement is the fact that it can operate at very great speeds up to 200 words a minute when automatic sending is employed at the transmitting station. For ordinary speeds a siphon recorder or Morse inker would be a much simpler and more economical arrangement, and either could, I think, be got to work well on the strength of signal that I heard at Lavallois.

Another method of recording employed at Lavallois consisted in the employment of a phonograph, the vibrations of the receiving telephone being used to operate a stylus engraving on wax in the ordinary way. When high-speed messages are being received, the phonograph is run very fast, while afterwards, the messages can be reproduced on a much slower running phonograph. In this way, it is possible to decipher by ear and write down messages which have been sent at far higher speeds than

FIG 8 PHONOGRAPH FITTED WITH TELEPHONE RECEIVER

could be recorded by anything other than automatic apparatus.

A phonograph fitted for the receiving of wireless messages in this manner is shown in Fig. 8. As will be seen, it is an ordinary Edison phonograph of the type that is now called a Dictaphone, though actually of much older make. The wax cylinder on which messages are recorded is in a horizontal position near the top of the instrument, the base of which contains a slow running electric motor which causes the wax cylinder to rotate. Above the cylinder is an arm which carries the recording diaphragm connected to a small sapphire point or chisel, which cuts a groove of varying depth on the wax as the cylinder rotates, as the diaphragm vibrates, and as the arm and chisel are caused to travel along a line parallel to the cylinder's axis. Above the diaphragm is mounted a Brown loud-speaking telephone receiver, minus its horn, any sounds of sufficient loudness, whether in the shape of Morse signals, or of music, or of speech, emitted by the loud-speaker being communicated to the engraving stylus, and recorded as indentations on the wax. It will be understood

that in this case there are two diaphragms, one, the diaphragm of the Brown loud-speaker, and the other the diaphragm of the phonograph, and that the former impresses its vibrations on the latter through a column of air of a couple of inches in length. This works quite well, provided the sounds are sufficiently loud, but no doubt a more sensitive arrangement would be obtained if both the diaphragms and the intervening column of air were suppressed, and the recording stylus connected directly to the vibrating reed of the Brown telephone. As you will hear, the instrument records wireless Morse signals very perfectly, and reproduces them in so good a manner that it is often difficult to distinguish the reproduction from the original. Music and speech are also reproduced with clearness, even when the original music sent by wireless is the result of a gramophone playing at the far end. In such a case, it is to be remembered that there are no less than eight transformations :

- (1) Sound to record :
- (2) record to sound :
- (3) sound to variations in electric current :
- (4) electric current variation to modulated electric waves :
- (5) modulated electric waves

to electric current variation: (6) electric current variation to sound: (7) sound to record: (8) record again to sound.

It is really surprising after so many transformations that the final result retains so much of the quality and other peculiarities of the original.

I will now start the phonograph going, and you will hear both Morse messages that have been recorded by wireless from Paris, Berlin, Moscow, Madrid and other distant places; and also actual speech and music transmitted over distances of several miles.

We will now put the amplifier into operation and listen for a transmission of wireless telegraphy sent from my office in Victoria Street, with the very small power of only about 10 watts. For the reception of this we must, of course, use the external aerial that we have put up on the roof, as the frame aerial could not be expected to receive with such a small amount of power. As you hear, Victoria Street is now sending in Morse signals the call sign "2 H K," which has been assigned to it by the Post Office. Having sent the call sign, a lady in Victoria Street is now going to sing. As I think you are able to recognise, the song is "Annie Laurie."

We are now going to have some more wireless speech and music transmitted to us by Mr. W. W. Burnham, from Lewisham. This is on a very short wave length, and, therefore, we expect to have no interference from other stations, because no one else is likely to be sending on such a short wave length.

For receiving this transmission from Lewisham we shall use a special arrangement of three-valve amplifier and two-valve note magnifier kindly lent for the purpose by Mr. Burnham.

The amplifier has three valves operating respectively as high frequency amplifier, detector and low frequency amplifier. Switches are provided, permitting the valves to be used in four different ways, viz.: (1) single valve, as detector amplifier; (2) two valve, one high frequency, one detector; (3) two valve, one detector, one low frequency; (4) three valve, one high frequency, one detector, one low frequency. The high frequency valve operates by means of capacity-reactance coupling for waves from 150 to 5,000 meters in length, and by capacity-resistance coupling for waves over 5,000 meters. A special design of circuit is used in which each valve has its

own filament rheostat, such rheostats being used to control the grid potential of the valves in addition to their usual function. The grid of the high frequency valve is normally operated about four volts positive, but the damping so introduced is destroyed by the use of magnetic reaction taken from the plate of the detector valve. Contrary to most high frequency amplifiers, the reaction is quite as easily controlled as in a one valve set, and there is no tendency for the set to fly into oscillation.

Owing to the introduction of damping on the first grid and its subsequent destruction by resonance of the reaction coil, the apparatus is remarkably selective in that it gives optimum amplification only on the particular wave length at which it is being operated.

As you hear, Mr. Burnham is now addressing the meeting by wireless from Lewisham, and now you can hear "Land of Hope and Glory" played at Lewisham on a gramophone. In addition to your hearing this, we are taking it down on the phonograph, and later on we will let you hear the music again from the phonographic record. Here it is, and as you hear, the tune is quite recognisable, in spite of the many transformations it has been through.

I now wish to show you a novel form of loud-speaking telephone receiver which was recently exhibited in London at the Institution of Electrical Engineers, by its inventors, Messrs. Alfred Johnsen and Knud Rahbek, two Danish Engineers, of Copenhagen. This instrument depends for its working, not on the varying attraction of an electro-magnet on an armature as does the ordinary telephone receiver, but upon the varying co-efficient of friction that takes place between two rubbing surfaces under electrostatic attraction. Telephone receivers working by reason of electrostatic attraction are very old. When condensers consisting of alternate layers of tinfoil and mica were first constructed, it was found that if an intermittent high potential was applied to the leaves, the condenser could be made to hum. On this principle was based Dolbear's electrostatic telephone receiver, which consisted simply of two thin metal plates separated by means of a thin mica washer round their edges, so that the plates formed an air condenser. The back plate was prevented from vibrating by means of a screw pressed on it from the rear, while the front plate, which was held near the

ear, would vibrate under the force of the electrostatic attraction between the two. This instrument, when operated by a microphone transmitter connected with a step-up transformer so as to make the potential variations as high as possible, would repeat human speech, and it was found that if the two plates were initially polarised to a high potential the sounds produced were made louder.

A variation of this form of electrostatic receiver which I have found to work quite well for wireless signals, is to use two thin bare metal plates with a piece of chamois leather between them. The chamois leather is preferably glued over the surface of one of the plates, while the other is held to the ear, with the leather between them. If the two plates are now connected in the plate circuit of an amplifier all the louder signals can readily be heard, though, of course, the instrument is nothing like so sensitive or so loud as a well-made electromagnetic telephone.

Nor is the employment of electrostatic attraction in conjunction with rubbing surfaces entirely novel for the purpose of producing a telephone receiver. As long ago as 1879, Mr. Conrad Cooke, lecturing in this room, showed an apparatus invented some years previously by the late Elisha Gray, of Chicago. This apparatus is illustrated in fig. 9, where, on the right, there is

lid of thin metal, the whole apparatus being connected to earth. To make it work, all that is necessary is for the handle to be turned so that the box rotates, and the operator, taking the line wire in his hand, should touch the thin lid of the box so that his finger rubs upon it as the box is rotated. It is then found that the varying electrostatic attraction between the rubbing finger and the rotating lid causes variations in the friction which throw the lid into vibration, so that sounds communicated to the microphone become audible, the hollow box acting as a resonator. I understand that Gray himself, at first thought that the effect was physiological and dependent upon living matter, but Tyndall, who investigated the subject, found that dead matter, such as pork rind, parchment, or leather, worked just as well as the human finger.

Then again, in the Proceedings for 1883 of the Institution of Electrical Engineers—or rather of the Society of Telegraph Engineers, as it was then called—I have found an account of what is called a static induction telephone invented by Mr. W. Moon. Fig. 10 is a reproduction of the instrument as depicted in Mr. Moon's communication. And here is Mr. Moon's account of his apparatus in his own words:

"While experimenting with Dr. Wright's tinfoil paper telephone, I noticed that, when the two sheets of

FIG. 9. ELISHA GRAY'S ELECTRO-STATIC TELEPHONE.

a microphonic telephone transmitter H sending undulatory currents from a battery MB through a step-up transformer, to line and earth. On the left-hand side of the figure there is an apparatus consisting of a circular hollow box D, which is mounted on an axle B upon a stand A, and can be rotated by the small handle B¹. The side of the box D away from the handle is closed with a

"paper were charged with high tension electricity, they were attracted and clung to each other, and that it required considerable force to pull them apart. This fact suggested to me the construction of the telephone I have the honour of bringing before the Society to-night.

"One sheet of tinfoil paper is fixed to

FIG 10 MOON'S STATIC INDUCTION TELEPHONE

a cylinder, with the metal surface inside, and another sheet of similar paper rests on the surface of the thus covered cylinder, with its metal surface outwards, and is attached by a thin cord to the centre of a diaphragm, so that, on rotating the cylinder, the diaphragm is pulled in the direction of rotation of the cylinder by the friction between the two surfaces of paper.

By charging the two sheets of paper with high tension electricity from an induction coil, the friction is increased, and the diaphragm drawn in at each vibration of a rheotome, so that the vibrations of the rheotome are exactly reproduced in the telephone; and, by substituting a Reis transmitter in the primary circuit in place of the rheotome, the pitch of each musical note of the transmitter is exactly reproduced in the telephone.

The loudness of the telephone is proportional to the surfaces of the paper in contact, or to the capacity in farads, and most probably to the square of the tension of the charge. It is, however, necessary that the power of the induction coil used should be proportional to the capacity of the telephone, as, if the coil is too powerful, sparking takes place between the two surfaces of the paper. With the larger telephone on the table, I find that a coil of 1-inch spark gives the best results.

Mr. Kempe has improved the loudness of the telephone by pressing the two surfaces together by a spring, and also by using powdered chalk between the two surfaces of the paper.

I have tried many different forms of transmitters that Mr. Preece has kindly supplied me with, and find that the original form of Reis transmitter gives the best result.

What Dr. Wright's tinfoil paper telephone was I have been unable to ascertain, though I imagine that tinfoil paper is merely paper and tinfoil glued together.

Elisha Gray's apparatus will be found described in text books; but I fancy that Mr. Moon's arrangement had been entirely forgotten until I accidentally unearthed it in looking through old numbers of the Proceedings of the Society of Telegraph Engineers for quite another purpose.

In connection with their apparatus, Messrs. Johnsen and Rahbek showed a very remarkable experiment which I hope to repeat. If you take a lithographic stone, which is not an insulator, but a very bad conductor, and glue on the back of it a piece of tinfoil, and then lay on the flat face of the stone a brass plate two or three inches in diameter, taking care that the surface of the stone and the surface of the plate are both quite flat so as to make good contact all over, it will be found that if the plate and the tinfoil respectively are connected up to a source of high potential, say

of several hundred volts, the amount of current that passes is exceedingly small, being, in fact, only one or two micro-amperes owing to the great resistance both in the stone itself and at the surface between the stone and the brass plate. Further, it will be found that while the fall of potential through the stone is comparatively small, a very large fall of potential—about 90 per cent. of the total—takes place between the two surfaces of the stone and the brass. Furthermore, whereas with no potential applied the brass plate can be easily rubbed about on the surface of the stone, when a potential say of 200 volts is applied the friction between the two becomes so great that it takes from three to five pounds pull to move the brass plate, the friction increasing and decreasing instantaneously as the potential is applied, or removed, or varied. As the total resistance is so great, very high resistances, as, for instance, the human body, can be inserted in the circuit without making any difference to the results.

The large pull required to move the brass plate when electrified can be shown by means of a spring balance, or, if the stone be inclined at a considerable angle with the brass plate electrified, the latter will stick wherever placed on the stone, sliding down immediately the moment electrification is removed.

On the hand-side of the figure will be observed a cylinder which is made of highly polished agate, into which a metallic core has been glued with water glass. Agate, like lithographic stone, is a very poor conductor of electricity, but conducts just sufficiently to allow any potential applied to the core to reach the surface of the cylinder, and also to leak away again when the potential is removed.

The agate cylinder is caused to rotate, and round it is stretched a thin metallic band one end of which is connected to a diaphragm M, the other end being kept taut by means of an elastic india rubber band marked S in the figure.

The tension on S and the extent to which the metallic band is wrapped round the cylinder, should be capable of adjustment. The left portion of the diagram shows how the apparatus is worked for the reproduction of speech from a microphone. T is the microphone supplied with current by a 2-cell battery and working through a 1 to 10 step-up transformer Tr; m is an adjustable shunt resistance across the primary of the transformer, by means of which the strength of the currents operating the transformer can be controlled. The secondary of the transformer is inserted between the filament and grid terminals of a thermionic valve,

FIG. 11. JOHNSEN & RAHBK'S TELEPHONE: DIAGRAM OF CONNECTIONS

Messrs. Johnsen and Rahbek have applied this principle to make a loud-speaking telephone which certainly gives remarkable results. Fig. 11 shows a diagram of the arrangement they employ. On the right-

connection being made to the grid through a potentiometer and battery P, whereby the grid voltage can be regulated. A battery A, of not less than 150 volts, is employed to supply the plate current, the voltage

FIG. 12 JOHNSEN & RAHBK'S TELEPHONE: GENERAL VIEW

actually applied being regulated by the adjustable high resistance R . Provided the resistance R is less than about 20,000 ohms, the condenser C shown in dotted lines, can be omitted. L is a self-induction choke coil of from 3 to 10 henries, through which the continuous battery current can pass, but which offers great impedance to the rapidly varying speech currents. By this means the metallic band is kept permanently at a high positive potential above the agate cylinder. Fig. 12 shows an apparatus constructed on this principle which has been put together in my laboratory. The agate cylinder, which is mounted on a vertical axis, is seen at the top, and is about two inches in diameter and about two inches long. The metallic band, which is nearly as wide as the cylinder, in this case is made of thin nickled copper, with the nickled side in contact with the agate. Messrs. Johnsen & Rahbek, who kindly supplied me with this nickled band, tell me that the best material for the band is rustless steel 0.02 m.m. in thickness. So far, I have not been able to obtain such thin rustless steel. Its advantage is that it does not wear out, whereas, after a few hours work, the nickel is worn away. The metallic band is connected at one end to an india-rubber band which, at its other extremity,

is adjustable, and at the other end to the centre of an ordinary gramophone diaphragm at the end of a trumpet. The agate cylinder is caused to rotate in the direction that causes the metallic band to pull on the diaphragm, at about 100 revolutions per minute, by a small electric motor contained in the box below the cylinder, which latter it drives through belt gear. The adjustable resistance on the side of the box is for regulating the speed of the motor, while the long adjustable resistance on the left-hand side of the figure, is the high resistance R of the diagram, in this case having a maximum resistance of 10,000 ohms. In the middle of the illustration, near the bottom, are the thermionic valve with its adjustable filament resistance, and the choke self-induction. We have dispensed with the potentiometer, as we did not find this of much advantage. For the 150 volt battery A of the diagram, we use 200 volt continuous current from the supply mains.

We will now put the apparatus to work, and, as you will see, when I talk into this microphone which I hold in my hand, the instrument reproduces what I say very much louder than my own voice. For the reproduction of wireless signals or speech, all that is necessary is to connect up the plate circuit of the receiving amplifier with the

primary of the telephone transformer. As you will observe, when this is done, and signals are received, the results are startling.

I now propose to explain to you a method by means of which anyone who possesses a wireless receiving set can obtain the correct time accurately to the one-hundredth of a second.

As you will observe it is now nearly eight minutes past nine, at which time precisely the Eiffel Tower in Paris commences to send out a series of 300 dots, regularly spaced, at intervals which are $1/50$ of a second less than one second. In each series the 60th, 120th, 180th and 240th dots are suppressed in order to facilitate counting.

Mr. F. Hope-Jones, of the Synchronome Co., Ltd., has kindly lent me a pendulum clock which beats seconds, for comparison with the dots. As you hear, the dots have now commenced, and as the intervals between them are rather less than one second the dots are gaining on the second-beating clock, and from time to time you will find that the dots and the clock beats coincide.

The method of using these dots for the purpose of getting the correct time is known as the Method of Coincidences, and constitutes an acoustic vernier. The observer listens to these dots in his receiving telephones, and listens also to the beats of his own second-beating clock which he is checking. By noting the time indicated by his clock at the moment of coincidence, as well as the number of the dot at which the coincidence occurs, it is easy to calculate the error of his clock to the one-hundredth of a second. For this purpose, it is necessary to obtain from Paris the exact times at which the first and the last dots were sent out. These times used to be sent out by wireless from the Eiffel Tower in Morse alphabet, but I understand they are no longer sent out, but can be obtained by those interested on application to the Eiffel Tower wireless station.

As already mentioned, the comparison is made by listening simultaneously to the wireless dots and the clock beats, and noting at which dot (i.e., as numbered from the beginning) close coincidence occurs. It is clear that, as the clock beats are spaced one second apart, and the wireless dots about $1/50$ of a second closer together, there will be four or five opportunities to observe coincidences. At each coincidence the time shown by the clock to be

checked is noted. As an example, suppose that the 45th dot occurs exactly when the clock to be checked shows 10hrs. 31mins. 2 secs. We first calculate the interval between dots from the figures obtained from Paris.

Assuming that the first dot occurred at 10hrs 30 mins. 10.27 secs., and the last (300th) dot at 10hrs. 35mins. 3.42 secs.

We then proceed as follows :—

	Hrs.	Min.	Secs.
Time of first dot	10	30	10.27
Time of 300th dot	10	35	3.42
Therefore, time of 299 intervals		4	53.15
Therefore, time of 1 interval			0.980
At first coincidence 45th dot (44 intervals) clock shows	10	31	2.00
Now, 44 intervals occupy 44×0.98			43.12
Hence, true time at 45th dot was	10	30	53.39
Instead of, as given by the clock	10	31	2
Hence clock error is			8.61
			Secs. fast.

The above gives the error of the clock as compared with Greenwich mean time. If, now, a second check be taken, say, 24 hours later, the exact gaining or losing rate of the clock may be found with extreme accuracy.

Putting the above procedure in few words, it may be expressed as follows :

- (1) Subtract the time of the first dot (as given by Paris) from the time of the last.
- (2) Divide the difference so found by 299 (this would give closely the figures 0.98 secs., which is the interval between dots).
- (3) Multiply this interval by the number of intervals between the first dot and that one at which coincidence was observed.
- (4) Add this product to the time of the first dot. This gives the true time at the moment of coincidence.

It may be thought that this method of obtaining correct time to the one-hundredth of a second is an altogether unnecessary refinement of accuracy, but it is of the greatest value where there is any question of an erroneous determination of longitude, and it altogether eliminates the most troublesome factor ever present in observatories, namely, the personal equation of the observer who takes transits every night from the clock stars.

I think it now only remains for me to thank the various people who have assisted me this evening. My special thanks are

due to Mr. W. W. Burnham, of Deptford, who sent these really fine musical transmissions from Lewisham, and to Mr. Frank Phillips, who has so skilfully worked the receiving apparatus. Then I wish to thank also Messrs. Johnsen & Rahbek, of Copenhagen, who have given me very useful information with regard to the making and operation of their apparatus; Sir Herbert Jackson, who has taken endless pains in procuring for me an agate cylinder; Mr. S. G. Brown, who has lent me a special differential microphone transmitter, and also a loud-speaking telephone; Mr. R. C. Clinker, of Rugby, whose ingenious model in explanation of the working of the frame aerial I have shown you; Mr. Basil Davis, who has lent the fine example of the 'Magnavox' loud-speaking instrument, and Mr. Hope-Jones, of the Synchronome Co., Ltd., who sent us that excellent specimen of the second-ticking clock. I wish also to thank my own assistants: Mr. Sidney Langley, who has made a large amount of the apparatus shown, and particularly the frame aerial, the six-valve amplifier and the loud speaker with the agate cylinder, and who has devoted an enormous amount of trouble to getting all this apparatus to work; and my secretary, Mr. A. W. Langley, who has also spent much time on the same business. I have also to thank Mr. Bradshaw, whose wirelessly transmitted voice you heard on the phonograph, the lady whom you by wirelessly heard singing in Victoria Street, and Mr. Davenport, who always presides so skilfully at the lantern on these occasions.

DISCUSSION.

SIR OLIVER LODGE, D.Sc., F.R.S., in proposing a hearty vote of thanks to Mr. Campbell Swinton, for his address, said it was evident that an immense amount of trouble had been taken in preparing the experiments that had just been seen and heard. He thought the Chairman assumed a great deal of knowledge on the part of those present. It was evidently not the first time that he had addressed them on the subject of wireless telegraphy, and they had now seen some of the latest developments, but it was well to remember the extraordinary character of the demonstrations. It sounded as though the Chairman had got a gramophone under the table and was deceiving his audience, but it must be remembered that all the disturbances had come through the ether and had been reproduced by means of little lamps. It was not obvious, but it was true, that those little

lamps had been doing the most essential part of the work. There the electron was harnessed, and the hot wire which was in the lamp was not for the purpose of giving light but for the purpose of supplying electrons, which evaporated from the hot wire. In that vacuum bulb there were a lot of electrons which were docile and obedient to every impulse which was given to them, and they were so quick in response that they could follow every fluctuation of the human voice. In fact, an interval of a thousandth part of a second was, as it were, a month to them; they could do all manner of things in that time. They had not the slightest difficulty in following everything, and if anyone had put one of the lamps out the whole demonstration would have stopped. The use of the magnifying valves rendered possible extraordinary developments. The practice of the art of wireless telegraphy was advancing with extraordinary strides, and those who were working with those valves were enamoured of their work, for the valves were most remarkable things. He believed that a great future which was as yet hardly realised, was before the method that made use of them, for they could be made to magnify a million times. By another kind of device a shouting telephone of greater power than those used before had become feasible, and already a voice could be magnified into an abominable noise as they had heard that evening — and what would happen when sounds were magnified a million times he really did not know. No one could tell what the result would be when one began to harness electrons in such a way as really to tap the energy of the atoms of matter. The present occasion was the first time he had heard the electrostatic telephone to anything like the extent that had been demonstrated by the Chairman. It was electrostatic attraction that was doing it. He doubted whether there was any need for a current at all. The reason the force was so great was because the two surfaces were so exceedingly close together. If one reckoned what the force was when one had 200 volts at a distance of about $1/1,000,000$ mm., over a fair area, one would see it was a very great force. It was, as the Chairman had said, several pounds — it might even be several hundredweights. Perhaps one of the most remarkable things was the detection in that room of messages from Paris or Nantes or any other distant place upon a frame of the size of that exhibited by the Chairman. Generally an aerial station was a large erection with aerials exposed high up and collecting the waves. No such arrangement had been used on the present occasion. There had been just the frame shut up in a building in the middle of London. Moreover, the Chairman had previously carried out a most interesting experiment with the apparatus he had shown. He put it into a copper box to screen it off, and put the lid on, and still it could be heard. A copper plate was known to be completely

opaque to short-waves, but whether it would be completely opaque to the magnetic aspect of the very long waves that came from the Eiffel Tower, he (the speaker) was uncertain, and therefore he had followed the experiment with considerable interest. He (Sir Oliver) had made the same sort of experiment a long time ago, in the nineties, with Hertz waves of a few yards long; but now waves were being dealt with that were thousands of yards long and they might be able to get through. It seemed, at first, as though they were getting through, even when the lid was on, but if the lid was soldered on or the box made in some way absolutely wave tight, then they were stopped. Therefore, it appeared that the copper box was really opaque and yet the thing was so sensitive that the sound could be heard even when the whole of the apparatus was shut up in a box that only had the narrowest chink open. Somehow even large waves got in through the chink and produced the effect, though there were other experiments, waiting to be done, before complete opacity could be concluded. He wished in conclusion, to call attention to the large amount of work that had been carried out by the Chairman and the skill that had been shown in doing the experiment.

SIR DAVID CLERK, K.B.E., D.Sc., F.R.S., in seconding the vote of thanks, said he had known the Chairman for a very long time and had seen him carry out very many experiments during the last thirty years. One of his chief characteristics was that he took a great deal of interest in other people's work and added to it his own work. He agreed with Sir Oliver Lodge, that the experimental work shown by the Chairman that evening was of very high quality indeed, and it was impossible to thank him enough for the trouble he had taken. The members of the Society also owed the Chairman a deep debt of gratitude for the trouble he had taken and the success he had achieved in placing their old and important Society in a greatly improved financial position. It was due to Mr. Campbell Swinton that during his chairmanship a Committee was formed which went into the question of securing more funds. Personally he wished to thank the Chairman most heartily and he was sure all the members would join him in that for his efforts on behalf of the Society. It would have been a great pity if the Society had had to leave this historic building, and that occurrence had been rather imminent at one time. The danger had now been averted, and the Society could continue in its old rooms, in which so many distinguished and original lectures had been delivered for over 150 years.

THE CHAIRMAN, in returning thanks, said he wished to point out that, although he might have taken some little part in helping the

finances of the Society by subscribing himself and by inducing other people to give subscriptions, the individual to whom most thanks were really due was the Secretary, Mr. Menzies. Mr. Menzies had personally found the very generous benefactor who had given the Society £30,000, and he, the Chairman, had no part in that.

The meeting then terminated

DRAWN WORK, EMBROIDERY AND LACE INDUSTRIES AT SWATOW.

The drawn-work industry was introduced into Swatow by missionaries 30 or 40 years ago. At first the making of drawn work was taught to converts as a means of earning a livelihood, but the work soon came to be produced on a commercial scale. During recent years, writes the U.S. Consul at Swatow, the demand has fallen off, partly as a result of the war, but as new designs are being adopted it is again attracting more notice. However, in the opinion of some persons interested in the business, this industry will never grow to be of great importance.

The centres of production is the Kityang district, and the number of workers is now estimated at 10,000. Although it is a household industry, the workers devote their whole time to it except during the harvesting of the rice crop.

Business is usually carried on in this way: A head worker or contractor will visit Swatow to buy material on his own account and then return to his village, where he distributes the material to workers, and at the same time settles the production price per piece with them. When completed he collects the work and takes it to Swatow for sale. More often he secures contracts from Swatow firms, in which case he is supplied with the cloth. Swatow firms buy or order from these contractors, and the goods are then sent to Hongkong or Shanghai for sale. A small retail business and some export abroad are done locally.

Grass cloth, Canton and Kityang, and some Shantung pongee have been until recently the only cloths used, but latterly Irish linen has been introduced. Prices are always on the piece basis. The most fashionable design is the "fillet drawn," that is, an imitation of the fillet lace pattern worked and drawn on the cloth. Another design for which there seems to be much promise is "mosaic," which was introduced, it is claimed, from Japan. There are about 1,000 workers engaged in this type of work. All drawn-work pieces are also embroidered.

White embroidery is of later origin than drawn work, having been produced commercially in Swatow only about 20 years. The seat of this industry is Chaochowfu, which for

many generations was noted for its embroidering of mandarin robes and theatrical dresses. There is now no demand for such work and the white embroidery has largely taken its place. However, embroidered scrolls and temple drapery are still being made. It is estimated that there are no less than 10,000 workers.

Unlike the drawn-work industry, there is an embroidery union, which includes about 20 shops. Beside these, there are five or six open shops. This is a union not of the workers but of the shops, for the purpose of discouraging outsiders from engaging in the business. The designing is done by men in the shops, but the cloth to be embroidered is distributed among the workers in their homes. These union shops control more or less the scale of wages of workers as well as the price to be charged Swatow firms. These shops do business only on order, and receive the material from the firm placing the order.

This industry seems to have a bright future, and attempts to introduce new designs are being made with some success. Owing to the demand local prices for embroidery have advanced about 20 per cent. In comparison with the embroidery of Europe, the Philippine Islands, or Canton, Swatow work is said to be inferior, but the attention now being given to the industry will doubtless result in its improvement.

The filet lace industry was started in the Swatow district about four years ago and in 1918 the output had reached commercial proportions, but the rise in silver exchange in 1919 brought production to a standstill, and it has never since revived.

Filet lace is made in two parts, namely, the net and the working of the design. Chaoyang district is the centre of the net-making industry, and it is claimed that as many as 6,000 persons were engaged at one time in that work. For the design, Kityang has been the principal seat of the work. The thread used in this industry is British.

It seems that the crochet industry was introduced by missionaries prior to the drawn-work industry, but later it practically disappeared. The demand for this lace in 1919 effected its revival, and the number of workers is now conservatively estimated to be 5,000. Iam-tsau, a village in the Chonghai district, is the most important centre. Others of less importance are Ampo, Tangleng, Phu Sua, and Ungkung.

The industry is conducted in much the same way as the drawn-work industry. Head workers come to Swatow to receive orders for goods and to obtain thread, and when they return they distribute these materials among the workers. A head worker can effectively control about 200 workers. These head women get the difference between what they receive for the work at Swatow and what they pay the workers. Their profits are said to be very handsome.

Only hand labour is employed in these industries, no machinery whatever being used. A drawn-worker's outfit consists of a pair of scissors, a needle, a thimble, and a circular frame or stretcher. The embroiderer uses a needle and a square frame. It is estimated that the value of the total production of drawn work and embroidery (including the cost of the cloth) in the Swatow district in 1919 was between £30,000 and £40,000.

TAR, ROSIN AND TURPENTINE PRODUCTION IN FINLAND.

The tar industry in Finland is very old and was formerly of considerable importance, but the present production is comparatively small, amounting to about 50,000 hectolitres (40,000 barrels) per annum. Of this amount, about 30,000 barrels are produced in factories and the remainder, in kilns, or charring stacks.

The rosin industry, on the other hand, writes the United States Consul at Helsingfors, is quite new. The first rosin factory was built in Finland by the Finska Kemiska A. B. only 10 years ago. Stumps were used as raw material and treated by a special method invented by the founder of this factory. There are now three rosin factories in the country. Three of the paper mills also manufacture fluid rosin for the manufacture of soap.

There are about 40 turpentine distilleries in Finland. All of them are small, as the raw material cannot be transported far. The Finnish distilleries can generally char from 3,000 to 4,000 cubic metres (cubic metre = 1.307 cubic yards) annually. The largest is that owned by the A. B. Tjarindustri and is situated in Suolahti. About 9,000 cubic metres of stumps are charred there each year. Among the other larger distilleries are the factory in Kenru, E. Math. Bonn's factory in Kolho, and a distillery in Multia, recently built by the A. B. Rafso Angsag. The total annual production of turpentine is estimated at about 1,000,000 kilos (kilo = 2.2 pounds), of which about 800,000 kilos are produced in dry distilleries, about 100,000 kilos in rosin factories, and about 100,000 kilos as a by-product in sulphate cellulose mills. About 40,000 cubic metres of charcoal are produced in the dry distilleries and somewhat more than that in the kilns.

The total value of the annual production of tar, rosin, and turpentine in Finland is at present about 18,000,000 to 20,000,000 marks (Finnish mark = about 1d. at present exchange).

About 70 per cent. of the factories belong to Finland's Tjar-och Terpentinkontorslag, a union which was formed about 10 years ago for the sale of their products. It is probable, adds the Consul, that all the factories will soon join this union.

IMPROVEMENT IN METHOD OF PLANTING CASSAVA.

Mr. A. B. Carr, a director of the Agricultural Society of Trinidad and a prominent estate owner, has furnished the United States Consul in Trinidad with the following note as to a method he has discovered of shortening, by about one-half, the time required for the ripening of cassava tubers:

"Hitherto the way of planting the cassava was in short portions of the stalk, measuring from six to nine inches long; but purely by an accident it has been found that when the whole length of stalk of a cassava plant is planted the tubers ripen and are fit to eat in $4\frac{1}{2}$ months, against the old method which involves at least 8 months. The manner of planting is simply to insert the lower end of the stalk into the ground not more than two or three inches deep; and in order to secure the growing plant against the force of the wind, if in an exposed position, the plant should be tied to a stake. Planting is usually done in the month of May. In new lands as much as 12 to 15 tons of fresh tubers can be obtained, whereas in old, partially worn-out lands, unless a liberal supply of manure is allowed, not more than six to eight tons of tubers can be depended on."

This, says the Consul, should have great importance in practically doubling the cassava turnover from estates growing it.

Concerning the uses of cassava in Trinidad, Mr. Carr writes:

"1. It is eaten as a vegetable, boiled in plain water.

"2. It is made into what is known as farine, which is a coarse form of meal.

"3. After expressing the juice, the dry tuber is grafted into a meal, which upon being exposed to heat on a flat iron plate is made into bread.

"4. The expressed juice is boiled down and certain condiments are added, thus producing casareep, which is the foundation of many good sauces.

"5. Starch is also made from the tuber, the method of manufacture consisting simply of allowing the expressed juice to settle, the heavy matter being precipitated and when dried forming the starch of commerce.

It is known that alcohol can be produced from the cassava, which also contains sugar. If the price of sugar remains abnormal for a lengthy period of time it is likely that scientists will turn their attention to the sugar contents of this tuber."

The cassava sauce known as casareep appears to have preservative as well as flavouring qualities and is an indispensable ingredient in the well-known West Indian dish, "pepper pot," which is especially popular in British Guiana, where casareep is manufactured in commercial quantities.

In connection with the industrial use of the cassava plant for the manufacture of alcohol,

it may be mentioned that an Englishman was recently in Trinidad and British Guiana, investigating districts most suitable for cassava growing, and it is understood that in British Guiana about 10,000 acres of land were purchased for such purpose on behalf of distillery interests in Scotland. It is reported that large areas of cassava land in Madagascar and in Brazil have also been purchased for the same interests.

NOTES ON BOOKS.

THE HUMAN FACTOR IN BUSINESS. By B. Seabohm Rowntree. London: Longmans, Green and Co. 1921. 6s net.

In the introduction and throughout, the author makes frequent reference to "the workers"; and from the context it appears that he really means wage-takers, as distinguished from capitalists, employers, salaried persons, and the remainder of mankind. His opinion of "the workers" appears to be rather low. For example, he complains of the workers as "unfamiliar with the intricacies of finance and the economics of industry" (p. vi), and he, in an evident spirit of altruism, regards it as his duty to point out to "the workers" and others a way of realising a high ideal of comfort and prosperity.

It is to be noticed that Mr. Rowntree not only complains of "the workers" but also declares himself "profoundly dissatisfied with industrial conditions as they are to-day" (p. viii), and the present book is an exposition of his scheme of reform, which appears to be based on the liberal sentiment of paying "the workers" something over the minimum which they will accept, the excess wage being, may be, in cash or in facilities.

The advantages of the proposed reform are explained or elucidated by an illustrative instance; and what is to happen when the illustrative instance has convinced the world? Our author affords a clue to his hopes by remarking "it is well to remember that much social legislation consists in making generally compulsory what voluntary experiment has shown to be desirable" (p. viii).

The illustrative instance on which the author's argument is based, is, however, of such a nature as to be somewhat unconvincing; the factory taken as a basis for the argument produces fine comestibles and dietetic specialties, the marketing of which may be much facilitated not only by advertising in its ordinary aspect, but by attention being called to the works, and a general sentiment as to production having taken place in an atmosphere of health, liberality and philanthropy.

Under the heading, Medical Inspection of Applicants for Work (p. 69), there are hints as to the importance of food products being produced by a healthy staff as secured by the

rule that applicants for work shall be medically examined, but "the only exception to this, rule is in the building department" (p. 70). Surely all artificers should be as subject to the human factor as are the other wage takers; and indeed to any practicable or desirable health factor.

As far as we can see, Mr Rowntree's book, although interesting, readable and manifesting a kindly sentiment towards "the workers," does not present any new view of things to the student of Economics, but it should serve to emphasise the need of caution in drawing general conclusions from special instances.

Although Mr Rowntree appears to be quite free from bias towards any particular school of political economy, his evident aspiration toward a statutory establishment (p. viii) of conditions such as he pictures, shows how completely he is at issue with Adam Smith's contention that regulation of wages by law destroys ingenuity and industry.

Our impression is that if a student of political economy were asked to deal with the case presented by Mr. Rowntree, his view would be something like this. Under publicity and clever management the wage fund (taking the wider view of the term) would rise rapidly to the enrichment both of the exemplar wage takers and proprietors; but with a partly corresponding deprivation in other factories. Voluntary imitation under statutory legislation would, *inter alia*, tend towards the reaction conditions touched on by Ricardo in Chapter V, and all the wages would fall to (or perhaps below) the "Natural Price" in Ricardo's sense of this term.

GENERAL NOTE.

VICTORIA AND ALBERT MUSEUM.—Students of early Chinese pottery will be interested in a case that has recently been placed on exhibition in the Loan Court. A number of friends of the Museum have combined to lend from their collections over fifty specimens of *Chien* ware, so called from the province of Fu-chien where it originated. The ware is covered with an intense black glaze showing bluish reflections, in which are generally developed brown markings, compared by the Chinese to hare's fur or the breast of a partridge. In certain other varieties the markings resemble tortoiseshell or drops of oil on water; in some the black has yielded place almost entirely to a rich "dead leaf" brown. The exhibit serves to emphasise the infinite variety of this type of glaze, and the vases and bowls of which it is composed display considerable diversity of shape. The majority are in the form of small tea-bowls, for Chinese and Japanese alike have found this dark brown glaze without a rival for enhancing the qualities of their tea. Most of the specimens in this case may be ascribed to the Sung dynasty

(960-1279), though a single Japanese example in the shape of a 17th century German tankard is there to sound a warning note against the danger of indiscriminate early dating.

MEETINGS OF SOCIETIES FOR THE ENSUING WEEK.

- MONDAY, NOVEMBER 28.** ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. A. M. Hind, "Processes of Engraving and Etching." (Lecture I.) Electrical Engineers, Institution of (N. Eastern Section), Armstrong College, Newcastle, 7.15 p.m. Dr. S. P. Smith, "Single and Three-Phase Commutator Motors, with Shunt and Series Characteristics." Mechanical Engineers, Institution of (Yorkshire Branch), Y.M.C.A., Albion Place, Leeds, 7.30 p.m. Mr. J. G. Graves, "The World's Money System." Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Mr. S. J. Perry, "On the Relation between the Course of Wholesale Prices of Commodities and the Market Value of various classes of Securities." Faraday Society, at the Chemical Society, Burlington House, W., 8 p.m. Mr. J. N. Greenwood, "The Effect of Cold Work on Commercial Cadmium." 2 Messrs. J. N. Pring and E. O. Ransome, "Reaction between Cathodic Hydrogen and Nitrogen at High Pressures." 3 Mr. F. H. Jeffery, "The Electrolysis of Aqueous Solutions of Alkaline Nitrates with a Lead Anode and an Electro-metric Determination of the Constitution of the Complex Anion Formed." 4 Mr. T. C. Nugent, "An Inhibition Period in the Separation of an Emulsion." 5 Messrs. N. R. Dhar and N. N. Mitra, "Induced Reactions and Negative Catalysis." 6 Dr. S. Judd Lewis and Miss F. M. Wood will exhibit and describe "A New Adjustable Thermostat for All Temperatures between 0 and 100 deg. Cent." Architectural Association, 34, Bedford Square, W.C., 8 p.m. Mr. Nigel Playfair, "Stage Design."
- TUESDAY, NOVEMBER 29.** Electrical Engineers, Institution of (N. Western Section), 17, Albert Square, Manchester, 7 p.m. Messrs. L. J. Steele and H. Martin, "The Cyc-Arc Process of Automatic Electric Welding." Civil Engineers, Institution of, Great George Street, S.W., 5.30 p.m. Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. C. M. Williamson, "Photography and Mechanics, Facts and Possibilities." Anthropological Institute, at the Royal Society, Burlington House, W., 8.30 p.m. (Huxley Memorial Lecture.) Mr. H. Balfour, "The Archer's Bow in the Homeric Poems."
- WEDNESDAY, NOVEMBER 30.** ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 4.30 p.m. Mr. Noel Heaton, "The Preservation of Stone." Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. H. H. Elvin, "Some Causes of Industrial Unrest, and a Remedy." United Service Institution, Whitehall, S.W., 2.30 p.m. Colonel M. Earle, "The Officers Training Corps." Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m. Prof. W. de la Mare, "The Reading of Fiction."
- THURSDAY, DECEMBER 1.** Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Captain G. de Havilland, "The Design of a Commercial Aeroplane." Camera Club, 17, John Street, Adelphi, W., 8.15 p.m. Madame Yevonde, "Women's Photography." Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. Messrs. L. J. Steele and H. Martin, "The Cyc-Arc Process of Automatic Welding." University of London, Imperial College of Science, South Kensington, S.W., 5.30 p.m. Mr. W. Bateson, "Recent Advances in Genetics (Lecture V.)"

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

FUND FOR PURCHASING THE SOCIETY'S HOUSE.

The amount sought by the Council to secure the freehold of the Society's House and to renovate the premises, as stated in the appeal recently issued to the Fellows, is £50,000.

The following is the first list of subscriptions to the Fund:—

	£	s.		£	s.
Anonymous	30,000	0	Sir Harry James Veitch	25	0
The Hon. Sir Charles A. Parsons, K.C.B., LL.D., D.Sc., F.R.S.	2,500	0	Sir Robert Usher, Bt.	21	0
Lord Bearsted	1,000	0	The late Sir Shapoorji Broacha ..	20	0
Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.	1,000	0	Henry Bubb, Esq., J.P.	20	0
The Earl of Iveagh, K.P., G.C.V.O., LL.D.	1,000	0	Lord Foley	20	0
Lord Leverhulme	1,000	0	Mrs. A. E. Llewellyn	20	0
Alan A. Campbell Swinton, Esq., F.R.S.	1,000	0	Carmichael Thomas, Esq.	20	0
Sir Charles Allom	500	0	John Augustus Voelcker, Esq., M.A., Ph.D., F.I.C.	20	0
Sir George T. Beilby, LL.D., F.R.S.	500	0	In Memory of Richard Roberts ..	15	15
Lord Blyth	105	0	"R.P.S."	12	10
Charles William Dyson Perrins, Esq., J.P.	105	0	William Henry Flanagan, Esq. ..	10	10
Ralph Brocklebank, Esq., J.P., D.L.	100	0	Sir Claude Hamilton Archer Hill, K.C.S.I., C.I.E.	10	10

The above list includes all subscriptions received up to November 26th. Further lists will be published in the *Journal* from time to time.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 5th, at 8 p.m.
(Cantor Lecture.) ARTHUR M. HIND,
O.B.E., M.A., Assistant-Keeper, Depart-
ment of Prints and Drawings, British
Museum, and Slade Professor of Fine Art
in the University of Oxford, "Processes
of Engraving and Etching." (Lecture II.)

TUESDAY, DECEMBER 6th, at 4.30 p.m.
(Dominions and Colonies Section.)
FREDERICK COATE WADE, B.A., K.C.,
Agent-General for British Columbia,
"British Columbia—The Awakening of the
Pacific." THE DUKE OF DEVONSHIRE,
K.G., G.C.M.G., G.C.V.O., will preside.

WEDNESDAY, DECEMBER 7th, at 8 p.m.
(Ordinary Meeting). EMILE CAMMAERTS,
"Literature and International Relations."
H.E. the Belgian Ambassador will preside.

FOURTH ORDINARY MEETING

WEDNESDAY, NOVEMBER 23rd ; MR.
ALAN A. CAMPBELL SWINTON, F.R.S.,
Chairman of the Council, in the Chair.

The following candidates were proposed for
election as Fellows of the Society :—

Anis, C. A. M., Calcutta, India.
Ellis, Alec R., Liverpool.
Keller, George J., Bloomsburg, Pa., U.S.A.

Kutar, Kekobad Rustomji, Bombay, India.
Lewis, Samuel Judd, D.Sc., F.I.C., Ph.C.,
London.

McCutcheon, Robert Thomson, F.S.A.A.,
F.C.W.A., Glasgow.

The following candidates were balloted for and duly elected Fellows of the Society :
Baillie, Andrew Francis, London.
Bliss, Ernest H., B.Sc., London.
Graham, Andrew MacIntyre, Liverpool.
Greaves, Richard Methuen, Portmadoc.
Morris, Squadron Leader A. S. O.B.E., R.A.F.
Rogers, Captain Archibald Clement Campbell,
Tringganu, Federated Malay States
Symington, Harry, London.

The Trueman Wood Lecture on "The Coming of Age of Long-Distance Wireless Telegraphy, and some of its Scientific Problems," was delivered by Professor John Ambrose Fleming, M.A., D.Sc., F.R.S.

The Lecture will be published in the *Journals* of December 9th and 16th.

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

FRIDAY, NOVEMBER 25th ; BRIG.-GENERAL LORD MONTAGU OF BEAULIEU, K.C.I.E., C.S.I., in the chair. A paper on "An Imperial Airship Service" was read by Mr. A. H. Ashbolt, Agent-General for Tasmania.

The paper and discussion will be published in the *Journal* of December 23rd.

MANN JUVENILE LECTURES.

Under the Mann Trust a short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, 4th and 11th January, 1922, at 3 p.m., by Mr. William Reginald Ormandy, D.Sc., F.I.C., on "Clay: What it is--Where it comes from--and What can be done with it." The lectures will be illustrated with experiments.

Special tickets are required for these lectures. A sufficient number to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply to the Secretary at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

WEDNESDAY, NOVEMBER 16th, 1921.

MR. BASIL OLIVER, F.R.I.B.A., in the Chair.

THE CHAIRMAN, in introducing Mr. Lyon, the author of the paper, said that when he was honoured by an invitation to preside at the meeting he accepted it very gladly, because he knew Mr. Lyon's enthusiasm and the way he had nursed the youngest School of Architecture into a flourishing concern. He thought the Royal Society of Arts was to be congratulated on having chosen modern architecture for the subject of the paper; it was rather refreshing to find new work being considered, because old work was so frequently dealt with. Modern work was beginning to have more attention paid to it now. Professor Riley had been dealing with Liverpool architecture in a series of articles in the local press, and Mr. Powys, who was present that afternoon, had been writing on the subject in the *London Mercury*, and there were many other signs that more interest was being taken in the matter. There was a general looking forward and rather less looking back.

The paper read was :--

MODERN BUILDINGS IN CAMBRIDGE AND THEIR ARCHITECTURE.

By T. H. LYON, M.A.,

Director of Design in the University School of Architecture, Cambridge.

It is difficult to fix a suitable period from which to begin a lecture on the Modern Architecture of Cambridge. The first breaking away from what may be termed "traditional Cambridge Architecture" took place in the Seventeenth Century, a breaking away which is represented by such buildings as the third court of St. John's College, the western half of St. Catharine's College, the whole of Clare College, excepting only the Master's Lodge, erected between 1705 and 1715, and the Chapel, erected between 1763 and 1768. Clare College was, however, according to Messrs. Atkinson and Clark, erected on more traditional Cambridge lines with pointed windows and battlements, which were altered to their present state probably in 1762. I find difficulty in accepting this statement as correct. Judging from the appearance of the building, I feel that the alterations then made must have included much more than the squaring of

FIG. 6.—DOORWAY, ST. JOHN'S COLLEGE.

the windows and the substitution of balustrades for battlements.

The architects of the Eighteenth Century struck an entirely new note in their work, a note quite alien to that of traditional Cambridge architecture. And if we consider such buildings as that erected by Gibbs at King's College, the University Library and the Senate House, we cannot but be thankful to these architects for their deliberate break with tradition. Anyone who appreciates architecture will, I think, admit that more than half the architectural beauty of Cambridge is due to these Eighteenth Century buildings. Without them the King's Parade would be dull indeed.

But the work of the Eighteenth Century architects scarcely satisfied the more romantic cravings of the Nineteenth Century. Perhaps scholarship in architecture had to some extent become discredited, or, it may be, that the classical type in its modern garb was too modern to be of interest to the first antiquarian enthusiasts. And the antiquarians were beginning to rule the roost. Be this as it may, with the exception of the Fitzwilliam Museum, erected in 1837, and Downing College, erected between 1807 and 1873, there has been up to our day, and there still is, a harking back to a pre-Eighteenth Century period.

The work of the Eighteenth Century is, I am aware, wasteful from the point of view of the later Nineteenth and Twentieth Century requirements. The apartments in the Gibbs' Building at King's College, fit for the sons of noblemen, are extravagant in view of the requirements of the average undergraduate of to-day.

The problem which had to be faced in the Nineteenth Century, and which presses more than ever now, is that of obtaining the greatest possible accommodation on an ever restricting area.

The colleges of Cambridge are, with few exceptions, greatly in need of funds, whereas the number of students desiring University education increases year by year; and if we consider that a college of over 200 students has housing accommodation for only 40 within its walls, we do not wonder that the palatial buildings of the Eighteenth Century are out of favour.

We will begin our review of Cambridge Modern Architecture with the work of William Wilkins in the Nineteenth Century. William Wilkins was, I am convinced, at heart in sympathy with the classical tradi-

tion of the Eighteenth Century. The Gothic court at Corpus Christi College for instance, is in disposition after the classical manner. Reconstruct the windows and you have what might have been an admirable adaptation of Seventeenth and Eighteenth Century Architecture to Nineteenth Century requirements. The work is dull just because Gothic detail is applied to a building classical in its balance and proportions. The windows and doorways in the block against the street have a particularly disconsolate appearance, for they lack any sort of connection either one with the other or with the parent building. The whole is rather suggestive of a family quarrel.

Wilkins was a purist in detail; Gothic or Classic, he must have one or the other, and so he cannot let his fancy play as did the builders of Brasenose College, Oxford, where we have a fusion of the two traditions undoubtedly interesting and pleasing in its gaiety.

William Wilkins was also in spirit an artist; he cared above all things for the appearance of his buildings. He felt, as every artist must, that there is a dull monotony in the mere repetition of set after set of students' rooms, exactly of the same proportion and plan. And, therefore, he cared little for his interiors, so much so that he has even placed windows down at the floor level where to have raised them to the normal level would have upset the classical balance of his exterior.

Unlike the buildings by Rickman at St. John's College, once inside the living rooms of a Wilkins' building Gothic all but disappears, for his classical bias reasserts itself in doorways and mantelpieces, and he is Gothic only in the treatment of what is common to his exterior and interior, viz., in the stonework of his windows. The Rickman buildings at St. John's College were erected in 1825, and the Corpus New Court in 1822. In comparing these two buildings, we realise that Wilkins was a much greater artist than Rickman. Corpus Christi College was saved from an architectural disaster such as St. John's College suffered at the hands of Rickman. We may pass over the abomination of desolation which Trinity College suffers from, erected between 1859 and 1868, by Salvin; and known as Whewell's Court, with the remark that this building suggests the blank despair aroused by tragedy without one relieving touch of comedy.

Now the problem which the Nineteenth Century architects had to solve, and which I have mentioned, viz., that of obtaining greater accommodation on a restricted area, had been very successfully solved in the Seventeenth Century. I refer to the buildings erected at St. John's College in 1674, probably by a pupil of Sir Christopher Wren, and also to those erected in 1679 at St. Catharine's College. The tradition then created might have developed further and successfully under the hands of as skilful an architect as William Wilkins, had not the palatial conceptions of the Eighteenth Century tempted him, and rightly so, to adopt a more classical treatment in his planning, while probably, some outside influence forced him to adopt Gothic detail. I discovered a note at the bottom of several of the drawings made by Wilkins for the work at Corpus Christi which is worth quoting:—"The contractor is to produce a plaster cast for all the sculptured and carved work from some building, to be approved by the architect of the College before it is executed." This quotation scarcely suggests a keen interest in Gothic detail.

William Wilkins failed, as I have stated, in an endeavour to apply pure Gothic form to a classical disposition, and it will be useful at this point to compare his work with that erected at King's College in 1891 by the late Mr. Bodley. Mr. Bodley felt and understood Gothic architecture, and although his work is the work of Bodley, his buildings are Bodley-Gothic. At times he indulges in Gothic idiosyncracies, almost to the point of disaster. We may, I think, consider as an instance of this the way his corner tower arrangement, in the building I refer to, is very nearly cornered out of existence. His works give the impression that on the whole he loves order, but also that he sometimes feels in his Gothic enthusiasm a desire to fight against it. In his passion for grace and refinement he gives to his work, at times, almost a touch of prettiness; as witness his chapel at Queens' College, which has a suggestion of prettiness more appropriate to an Anglican sisterhood than a College Chapel. There is an absence of the "grand manner" in his work, which seems to make it somewhat out of place in Cambridge. The "grand manner" is, to some extent, evident in the work of Wilkins, however much we may abhor his Gothic treatment.

The architects of the Eighteenth Century planted this "grand manner" in Cambridge, and once there, all modern architecture which fails to uphold it does, to some extent, sink into insignificance. I do not believe that the secret of the "grand manner" is a question of bulk, for plenty of modern buildings in Cambridge are bulky enough and to spare, but I do believe that it lies in breadth and simplicity of general conception. It is evident that the most unimportant doorway may have a touch of the "grand manner," as witness the doorway with the portcullis and crown over it in the Second Court of St. John's College.

The main fault of Cambridge Modern Architecture lies in a failure to uphold the "grand manner." Probably, owing to the multiplication of windows and therefore the decrease in plain wall space, which resulted from the necessity of obtaining more and smaller students' rooms under one roof, the problem of upholding breadth and simplicity became a very difficult one to solve. If we compare the Senate House with the Gibbs' building at King's College, we shall, I think, realise that the slight overcrowding of the windows in the Senate House places it second to the Gibbs' building as an example of the "grand manner" in architecture. I need hardly mention that the best example of this "grand manner" in Cambridge is Sir Christopher Wren's Library at Trinity College. As the most woeful examples of its absence in more modern Cambridge Architecture I should name the new buildings at Trinity Hall, which, by the way, should be compared with the delightful additions to the Master's Lodge at that College; both, and it is almost unbelievable, designed by the same firm of architects; all the modern buildings at Queens' College, and, in fact, wherever the so-called traditional collegiate architecture has been sold to colleges by the yard. This type of architecture is entirely negative and without a spark of interest. Better the correct proportion of Essex's work at Trinity and St. John's, however dull, than this doll's house rubbish. One feels that the architects who erect such buildings can never have felt Cambridge proper; that they have visited Cambridge only under the auspices of some antiquarian society, the members of which consider even the "traditional idol" at King's College almost too modern for their serious con-

sideration. The idea, which is yet, I believe, so prevalent, that Cambridge Architecture is just a delightful old-fashioned jumble of buildings, is quite an incorrect one for those who have eyes to behold. The architects of the Eighteenth Century continued the work of the master builders and architects of the Seventeenth, in giving a definite "lay out" to the University as a whole. We have only to note the compact arrangement of Clare College, the largeness of its conception and its completeness as a College, in order to view with horror this modern system of dotting buildings at all angles in the College grounds. A building in Cambridge succeeds as Cambridge Architecture only if it is dignified as a unit and at the same time gives further dignity to the College as a whole. This, then, is my main grievance against the architects of Modern Cambridge.

Now let me turn to modern buildings which appear to me to have that touch of the "grand manner" which is so essential to success in Cambridge Architecture.

Perhaps I should place in the first rank that most wonderfully beautiful building at Emmanuel College known as the "Founders" or "Westmoreland Building," rebuilt in 1811; Downing College, erected by William Wilkins (fellow of Gonville and Caius College, Architect) in 1807; the Fitzwilliam Museum, erected in 1837 by Basevi. The last I consider rather large in scale for Cambridge. It tends to crush the University Library and the Senate House, despite the fact that these two buildings are at some considerable distance from it. I think this will be felt by anyone who can carry scale in his eye. It is, however, delightful to walk slowly up the steps feeling the full dignity of this building, and while doing so an architect cannot but wonder whether the money will be forthcoming to provide a new University Library which shall not be insignificant in comparison with the Fitzwilliam Museum, or, indeed, with the front of the old library itself.

I find the "grand manner" in Scott the Younger's addition to Pembroke College, erected in 1883, and very much so in the addition to Sir Christopher Wren's Chapel at this College, made by Sir Gilbert Scott. The work of Scott the Younger suggests a carrying on of the tradition of the master builders as originated in Clare College. In viewing Scott's building, one feels that he

did something not only for Pembroke College, but also for the University as a whole, that he had grasped the ideal for University Architecture set us by the builders of the Seventeenth and Eighteenth Centuries. And, moreover, he is original without the least touch of idiosyncrasy; he does not despise the old notes, he knows how to rearrange them so as to express his own striking individuality. If you desire to study the work of this genius nearer to hand than Cambridge, you have only to visit the Church of St. Agnes, Kensington, and, above all, that of All Hallows, at Southwark. He is as versatile in these churches, and he expresses himself as freely there as he does in his buildings at Pembroke College. He does not strive to invent new mouldings, a practice on the part of architects which has been disastrous to so many modern buildings. He contents himself in this respect with the accepted forms, as does a musician with the notes of the piano.

Just as Scott the Younger grasped the necessity for the "grand manner" in his Pembroke buildings, so also did Professor Prior in his laboratory almost opposite, and also Sir Thomas Jackson in his Law Library in the same street, although in this last instance the breadth of the general conception is almost frittered away by insignificant detail. For instance, for my own part, I feel that the columns which are applied to the ground storey cut up the base of the building and destroy its scale. The long bays in this front are admirable and give great dignity to the whole block.

There is perhaps no architecture in Cambridge which we regret more than that of Mr. Alfred Waterhouse, although as sound careful building it is beyond praise. Mr. Waterhouse must have been indeed an architect with whom no builder dared trifle. It is sad that so much good building should fail so completely from the æsthetic standpoint. His work is full of thought, but with almost an entire absence of æsthetic feeling. It is of interest to note the influence of French Architecture upon Mr. Waterhouse, apparent in the front of Pembroke College, facing Trumpington Street, and here his hand is less heavy than in his building at Gonville and Caius College. The tower to this latter building is little short of a monstrosity. It crushes the Senate House and the University Library, and might well be considered a public nuisance which the authorities of

Gonville and Caius should be asked to remove. I am well aware that the architecture of every man of note is of interest, and also that Cambridge will, because the work of so many important architects is represented in its modern architecture, become a town much visited by future architects for the purpose of studying work of the Nineteenth and Twentieth Centuries; nevertheless, too big a price may be paid in the cause of interest, and I believe that the tower which I have vigorously condemned does so much damage to the architectural effect of the King's Parade that it should not be spared simply because it is the work of Mr. Waterhouse.

While we are, in imagination, on the King's Parade, I want to draw your attention to the range of buildings belonging to King's College and facing Trumpington Street which were added to the Wilkins building by Sir Gilbert Scott in 1870. We have here a very clever handling of what might perhaps be called Wilkins' Gothic. I feel that Sir Gilbert Scott has given to the Wilkins style just that unity between mass and detail which Wilkins in his work at King's College failed so conspicuously to obtain. As neo-Gothic this building is admirable for its date. It may lack the grace of Mr. Bodley's Gothic building in this College, but it has more substance, a greater sense of strength, and is more definitely an architectural composition. It is, I feel, much nearer in character to the work of the late Mr. Pearson than to that of Mr. Bodley.

The new range in Sidney Sussex College, by the late Mr. Pearson, does seem to me to be lacking in grace. The depressed arches to the cloister, the over-mullioned windows and the way feature elbows-out feature do together produce an effect which is architecturally ungraceful. At the extreme, Mr. Bodley is perhaps over-refined and Mr. Pearson somewhat coarse. As instance of this I would cite Mr. Bodley's Chapel at Queens' College and the building by Mr. Pearson which we have just been considering. Perhaps graceful architecture has just that touch of "damned nonsense" about it which escapes the effeminate; in other words, it has the "grand manner" which characterises a personage of unmistakably high breeding. A very good example of what I mean by grace in architecture is the "Malting-House," which is the work of Mr. Dunbar Smith and the late

Mr. C. C. Brewer. This building is also an example of the "grand manner" as it applies to quite a small building. The "grand manner" has, as I have stated, little to do with the largeness or the importance of a building, it depends for its existence far more upon the relationship between the components and the whole. And I think it is just because this relationship between the components and the whole is somewhat lacking in the new buildings at Emmanuel College that they fail to impress us as they should. There can be no denying that many of the features in this building, when considered apart from the whole, are both graceful and charming, but they fail to enhance the general effect. It may be that the lack of co-ordination is largely due to the architect's use of small rubble for his interstices. The effect is rather as in writing, where we are bothered by too many full stops owing to the shortness of the sentences. Without in any sense wishing to detract from the appreciation justly due to this original and charming addition to Cambridge Architecture, I must point it out as an example of the use of invented moulding, which I have taken the liberty of condemning earlier in this lecture. I note, in this building, the influence of the supreme destroyer of all classical feeling in moulded work. The building has been given thereby a touch of affectation which is alien to the general conception of the architect.

The lack of co-ordination, which means the absence of the "grand manner," is often due to the architect's hesitation in his design between a vertical and a horizontal treatment. This hesitation is well exemplified in the new building in the third Court of Christ's College, and the loss produced thereby becomes apparent if we compare this building with the Gibbs' building at King's College. Notice the dignity given to the King's building by a perfect balance between the horizontal and the vertical treatment, and then note the lack of dignity produced by the hesitation between these two treatments, conspicuous in the Christ's building.

There is a sense of the inevitable, of a decision taken and uncompromisingly expressed, which marks architecture after the "grand manner." And, what is far from being true in fact, a sense of the easily accomplished, a sense that anyone could have done the same; just as the manners of the highly bred appear so simple and so

facile, when in reality they are the result of a highly complex organisation composed of subtleties which are foreign to other than the genuine article. It is the "grand manner" which marks the work of a real genius.

We have, I think, in Cambridge, three definite types of modern architecture. We have architecture which is after the "grand manner," architecture which expresses the picturesque, and architecture which is wholly negative in character. I have named the buildings which seem to me to uphold the "grand manner," and of buildings which are successful examples of the picturesque I would mention the Henry Martyn Hall, erected by Professor Prior in 1887 as being in the first rank. This building might perhaps be considered as picturesque after the style of the "grand manner," for it has very much more dignity than generally falls to the lot of picturesque architecture. The same may be said of the entrance to the new buildings at Emmanuel. This entrance seems to want but a touch to bring it altogether on to the side of the "grand manner." The picturesque touch is, I believe, due to the use of rubble filling and also to the character of the hood moulding.

The carving over this doorway by the late Mr. Broadbent, who also executed the plaster ceiling in Sidney Sussex Chapel, is very delicate and beautiful. It is almost over delicate for exterior work in this country with its smoke-laden atmosphere. The new buildings at Magdalene College are also, I feel, eminently successful if viewed from the picturesque standpoint. Almost the best example of purely negative architecture is, I think, the range at Jesus College, forming the east side of the Chapel Court. Notice what a travesty of the beautiful entrance gateway to this College is the central feature of this building.

We have no modern churches in Cambridge which are of any architectural interest, excepting All Saints, opposite the entrance to Jesus College, built from the designs of Mr. Bodley. The spire to this church is, indeed, beautifully proportioned. The decoration of the interior is by Mr. William Morris, who was also responsible for the decorations to the ceilings of the nave and tower in the Chapel at Jesus College.

The work of Mr. William Morris at Cambridge is of great interest. Perhaps the very best example of his "neo-mediaeval" architecture is the decoration and the coloured

windows to the Hall at Peterhouse. The screen painting and the roof were erected by Sir Gilbert Scott in 1870. When we consider the Gothic horrors which this period brought forth we cannot but realise how great was the genius of Mr. William Morris. The chief characteristics of his work are striking individuality, intense refinement and a certain note of sadness. His colour schemes lack any touch of gaiety. They are rich and almost sombre in their richness. They go just as far as puritanism dare go without taking one step over the mark. He is, in his conceptions, very much under the spell of one mood, and he has refused to let himself think or act outside it. You say to yourself, as you review his work, "something held this man back." Was it that his horror of vulgarity made him too afraid of committing it?

The work of Mr. William Morris and his coterie has become the work of the past more definitely than the mere lapse of time between his life and ours would justify. It is less the basis of a forward movement than a sudden birth and complete development, a beginning and end in itself. The immortal spark which kindles the enthusiasm resulting in further effort and fresher expression, ever new and ever old, is not there. The work is not that of an architect proper, but rather of a cabinet maker, a worker in precious stones and a painter-decorator. We are indeed thankful for this work, the refinement, delicacy and interest of which is obvious; but there is just a feeling that it would be safer if kept under glass.

The appalling increase in the cost of building since the war has led to a type of building in Cambridge which is very much on American lines. I refer to the latest buildings erected for the purpose of the study of science. During my visit to America in 1918 I made a serious study of the architecture of that country with the view of adopting a similar treatment in England, should the opportunity of doing so occur. On my return to England I realised that the absence of brilliant sunshine would make it extremely doubtful whether or not such an experiment would be successful. In America the least projection casts a deep shadow, and this surface architecture is saved thereby from the poverty stricken appearance which would almost inevitably be a consequence of its use in this country.

The new buildings on Coe Fen for the School of Engineering are purely American in character. They present a baldness which only American sunshine could relieve. In our climate they are naked almost to the point of indecency. I have little doubt that American practical architecture forms a basis upon which to erect cheaper and perhaps more practical buildings in this country, but success in that direction can only be obtained by careful adjustment to suit the character of the English climate. We must so design our buildings that we obtain shadow effects on all but our most hopelessly dull days. Such deeply shadowed trees as the oak and the elm and the beech teach us this lesson, trees which are not common in America, where the lighter maple abounds.

The chimney to the buildings I have just mentioned is extremely graceful and groups admirably with the landscape when viewed from the Coe Fen side of the Peterhouse old wall. Some people may consider it out of place in Cambridge, but few, I should imagine, would deny its grace.

A very satisfactory science building is that erected for Parasitology, by Mr. Redfern, for here we have a quite successful attempt to adjust an American treatment to our own climate. This building is simple and altogether pleasing and, so to speak, "at home," even in Cambridge.

A building does not necessarily fail from the æsthetic standpoint merely because it does not suggest the particular use for which it was erected. On the other hand, it is very much the upholding of its purpose in use which gives the architect his best chance of presenting new æsthetic expression. The building by Professor Prior in Downing Street is undoubtedly a Science building, whereas those in the Court of the main block might almost as well be a new woman's college. As I have stated, I admire Professor Jackson's front to the Geological building, but this architecture is not really expressive of its use, despite the carved representations of prehistoric animals which adorn its base.

There is one more Science building which should be mentioned as deserving our grateful praise. I refer to the National Institute of Agricultural Botany. I hear that the architect claims proudly that it does not represent "Architecture"; but, to my mind, it has just that truly architectural proportion between mass and space

which is the basis of all that makes for the "grand manner."

Of the two Women's Colleges in Cambridge, Newnham is rather over-expressive of its use. It has somewhat the appearance of a ladies' drawing-room turned inside out. Perhaps this effect is due to the over use of white paint, although taken as a whole, it does suggest that the architect could not take the idea of University Education for women quite seriously. The architecture (if I may use the word in this connection) of Girton College is so bad and depressing that we may pass it over with the remark that it is overdressed to the point of vulgarity.

If in this paper I have been severe in my condemnation of much of the Modern Architecture of Cambridge, I have, I trust, left the impression with you that we have also a great deal to be thankful for. It is rarely that our architectural failures are devoid of any interest whatsoever, where architects have attempted more than a merely negative collegiate architecture. I feel that many architects who have been privileged to leave their impress upon Cambridge have been just a little afraid of themselves. They have not all given quite of their best. The knowledge that you have a real chance of marking yourself for good or bad is always unnerving. Architectural mistakes cannot be buried away in either Oxford or Cambridge; and he would be indeed a bold man who, while adding to University Architecture, did not at times feel his confidence in himself shaken. Moreover, College authorities do not make easy clients. It is a difficult matter to satisfy all the members of a governing body, consisting of 30 or 40, or even 12, fellows, without lowering your æsthetic standard to some degree. So that it would be unfair to judge all modern Cambridge Architecture upon the assumption that a free hand had been given to the architect. As a matter of fact, a free hand is rarely willingly given to an architect in Cambridge, and it is for him either to get what he wants by the exercise of patience and reasonableness, or if these fail to secure him freedom, to withdraw altogether. There are in Cambridge two parties (reviewing architecture from two diametrically opposed standpoints) composed on the one side of those who believe in advance and the "grand manner," and, on the other, of those who hold fast to past methods of expression and prefer the

picturesque. The true antiquarians are often on the side of the former party, while the general compromisers swell the ranks of the latter.

There is perhaps no body of men in the world which fears derision more than the governing body of a University College. They will always, if possible, anchor themselves upon the rock of past ages which it is irreverent to ridicule. Thus the standard most acceptable to them is just the type of architecture which fails to incite that praise from some which almost certainly means the condemnation of others. They are satisfied if by general consent the addition to their College "does not hurt the older buildings." However, it is impossible to live in Cambridge without becoming aware that a new generation is gaining authority, a generation which believes in its own age and will have none of this deadening compromise. And I feel that there is coming shortly an opportunity for architects of adding to the beauty and interest of Cambridge Architecture to a degree even more startling than that which the architects of the Eighteenth Century used to such advantage.

DISCUSSION.

THE CHAIRMAN (Mr Basil Oliver, F R I B A), in opening the discussion, said the paper had been an extraordinarily interesting one. He thought it was a very happy idea to show slides of American work, so that it might be contrasted with English work. In the slides that the author had shown of Cambridge architecture, he thought at first that the best and the worst were put next to one another purposely, but it was really only a coincidence. In his opinion Girton was about the worst, and the slide of of the new Agricultural College, which came next, was most delightful and formed a charming contrast. At the beginning of his paper the author referred to Gibbs' "deliberate break with tradition" when he produced such buildings as the University Library and the Senate House. The eighteenth century architects very rightly worked in the style of their time instead of in a past dead one. In other words, their work, like that of their predecessors, was a living architecture, less picturesque but more refined and scholarly and yet still collegiate in feeling. With the coming of the first antiquarian enthusiasts in the nineteenth century Cambridge, like the rest of the country, suffered from the blight of Victorianism. It might be called fancy dress architecture, because it was not quite serious or sincere; it was in fact, almost as shallow as the art of the scene painter and was totally lacking

in the real spirit of Gothic. Such ill-digested harking back had always been a harmful curb to free development, though he would be the last to deny the value and even necessity of tradition for the inspiration of modern work. Wilkins' Gothic Court at Corpus, though hardly comparable with the Houses of Parliament, had one characteristic in common with the latter, namely, Gothic features on a classic body. The author had likened that kind of architecture to a family quarrel, and he thought the simile was a good one. It was difficult to condone Wilkins' lack of interest in his interiors. To place windows down at the floor level for the sake of external effect was inexcusable and might almost be termed architectural snobbery. It was surely a sign of incompetence to design inwards from a preconceived elevation. Planning for convenience and comfort should of course come first as an essential. When the elevations came right, in unison with the plan, then the problem might be said to be successfully solved. Wilkins seemed to have made it his rule to be classical indoors and Gothic outdoors, in one and the same building. Such inconsistency and hesitation were deplorable. It was no wonder that the result was dull and lifeless, but for that the prevailing romanticism had to be thanked. The note at the bottom of several drawings made by Wilkins for the work at Corpus, quoted by the author, made him wonder if the architect was lazy or merely lacked self-confidence. Perhaps he had to copy at the bidding of his antiquarian employers, and it was more charitable to make allowances for that. Mere copyism was not art and never could be; the country suffered from it still and it accounted for a great deal of uninspired and bad work. The author touched on that elusive quality known as the "grand manner." To produce truthful building small rooms should have small windows, and it was hard—though he did not say impossible—to reconcile a multitude of small windows, as necessitated by undergraduates' rooms, with dignity and the "grand manner." As the author had said, in many instances at Cambridge palatial buildings had very small accommodation, and that showed that the "grand manner" if misunderstood could have very inconvenient consequences. Wren had a much easier task in the Library of Trinity College, which the author mentioned as the best example of the "grand manner" in Cambridge. It was a somewhat intangible quality, but it was as necessary to good architecture, whether great or small, as balance and right proportion. In forming an opinion on modern work, the difficulties of the custodians of old University buildings in making unavoidable additions from time to time should be taken into account. Colleges must sometimes expand or be otherwise altered to meet modern growth and requirements, and to do that successfully, without spoiling the work which existed,

was the supreme test of an architect's ability. The Fitzwilliam Museum was a case in point. That was described to him by a friend only two days ago as the only complete architectural thought in Cambridge, and he did not envy the task of the architect called upon to add to it. As his friend said, "You can't add anything on to the side of a watch." The author had said in his paper, that the governing body of a University College was usually satisfied if by general consent the addition "does not hurt the older buildings," and that was a very laudable idea as far as it went. The governing body should make sure they got the right architect, and then trust him. He agreed with the author in his intense admiration for the work of George Gilbert Scott, or "Scott the Younger," as he was often called; he was indeed a great architect, whose work should be studied by all students of architecture. It was to be hoped that his very distinguished son, Giles Gilbert Scott, the designer of Liverpool Cathedral, would one day have an opportunity of adding to the interest of Cambridge by producing there an example of the work of the third generation of hereditary genius. The reference made in the paper to the work of William Morris intensified his regret that there was no building in Cambridge designed by Morris' friend, Philip Webb. Had the two collaborated, Cambridge would have become even more of a Mecca for the architectural pilgrim. He greatly liked the note of optimism on which the author concluded his paper. Having seen the author's own very beautiful work in the Chapel of Sidney Sussex College—which he was too modest to refer to in the paper, except to praise his carver—he for one could testify that the author had practised what he had preached, and had added to the beauty and interest of Cambridge architecture. He believed Mr. Lyon had some slides of that work and was sure that every one present would be very glad to see them.

(Mr. LYON exhibited and explained the slides).

MR. A. R. POWYS, A.R.I.B.A., said he was sure everyone present had very much appreciated the privilege of listening to the author's paper on the architecture of Cambridge. It was exceedingly difficult to give an adequate description of modern buildings and to point out fairly what was good and what was bad in them. There were many points in such a consideration that made a man who was an architect himself hesitate before he gave a definite opinion. The author had given a description of the qualities of the architecture at Cambridge, with a kind of sidelight on the possibilities of future development, in a very fair spirit. Personally he found it a little difficult to grasp at once what he thought was a new meaning the author had given to the old expression, "the grand manner." He did not know whether he had been wrong or

not, but he had always associated the "grand manner" with the works of the great eighteenth century men, such as Vanbrugh, Campbell and Kent. The author also referred to picturesque architecture. He thought the words "grand manner" and the word "picturesque" had perhaps gained for themselves recently a meaning which they did not have originally, particularly "picturesque," which now carried with it a kind of sneer. The author showed a slide of the "Malting House," a very beautiful little building which Messrs. Smith and Brewer had repaired and altered, and described it as being in "the grand manner." Personally he would have said that it was picturesque, using the word "picturesque" in its true and original meaning. That of course was a minor point, and if by the expression "the grand manner" was meant fine architecture, it was easy to accept it. With regard to the author's reference to the work done by William Morris as an isolated feature in the progress of art, personally he did not consider that was so. It was true that William Morris himself was so versatile and had such a mastery of so many arts that there was no one who could follow him in that way, and in that sense he considered that his school and the feeling he put into his work were dead, but he felt that William Morris and his friend Philip Webb had done more for modern architecture and for the architecture that was to come than perhaps any two men of the last century. He held that opinion very strongly, and he fancied that possibly the excellent work done by the author, which had been shown on the last slides exhibited, was largely due to the work of William Morris and Philip Webb, although the author might be quite unconscious of it. He knew that the Chapel of Sidney Sussex College was in a manner which neither Morris nor Webb would have used, but at the same time there was about it a spring of inspiration, a desire to advance rather than to copy and imitate, which was perhaps at the base of their work.

MR. HALSEY RICARDO, F.R.I.B.A., said he had been exceedingly interested in the paper and in the slides that had been shown. He was very much impressed by the author's remark about the almost promiscuous way in which Cambridge had been allowed to develop of late years, and how buildings had been dotted about in the College grounds without any preconceived plan. Personally he thought that was a very serious but a very just criticism of the College authorities. With reference to the author's suggestion that the tower of Caius' College should be removed, he would deprecate any such action. The construction was sound and very fine in a way; the building was well planned and carried out with the sincerity that Waterhouse always exhibited. It might not be a sincerity that was acceptable at the present time,

but the building was sincere, workmanlike and craftsmanlike, and, apart from the absence of aesthetic feeling, it was a fine building and was entitled to a respectful preservation. It must be remembered that there was such a thing as fashion in architecture, and that fashions changed. He could remember very well the time when it was considered a mark of culture amongst undergraduates in Oxford to wave Keble College away with scorn; if anyone had a word to say for it he was without the pale. With regard to the expression "picturesque architecture," to which the author and Mr Powys had referred, he took "picturesque architecture" to mean fundamentally such architecture as a painter would like to represent in a picture. A painter in the real sense of the word, an artist, was of course a poet, and what concerned him was not so much perhaps the actual appearance, although that received consideration, as the sense and atmosphere of humanity. It was wrong and absurd for an architect to attempt to build picturesquely. A building became picturesque because successive generations of men had lived in it and hoped and feared and suffered in it, and had also developed it, as the need arose. A very simple test was to think of one's feelings when contemplating a ruined abbey or other ancient building. It had a pathetic interest. The ruin in itself might not be beautiful at all, it might be shapeless and ugly, but it was so charged with human history that it appealed to nearly everybody. He thought no new building could be called picturesque, because it lacked that human quality. It had, however, some human qualities: it had the architect's and the craftsman's care and interest in the matter, but that was scarcely sufficient. Time was required to develop the picturesque, and that was why certain buildings such as museums and galleries could hardly be called picturesque. On the other hand, many such buildings had an element of romance in them, such as the Senate House and Library of King's. He might mention that Wilkins built the National Gallery and also University College in Gower Street, and he did not know any more romantic and dramatic or picturesque buildings of their kind than those two, except perhaps the British Museum, which was another example of magnificent, grand, picturesque and romantic building. He would not speak disrespectfully of College Dons any more than he would speak disrespectfully of the equator, and he quite understood their difficulties, but he thought it should be vociferously declared that architecture was a living structural art, and that, although it was based on tradition of craftsmanship, style and so forth, and had a varying vocabulary in different ages, real architecture was a living affair. Therefore the feeling that in making an addition to a College or any other building one must be careful not to hurt the building was not so true as it sounded, although it was true in a

sense. Taking an example such as the Inigo Jones front to Worcester College, which was strictly classic, formal and severe in a way, with the most charming congeries of old buildings alongside, the combination was most delightful. There could be a great deal too much insistence upon an addition being made so as not to hurt the old building, and it led to a tendency to recall the past, when the past was out of tune with the present day. People now had different views and different ideals, and had also different methods of construction and different materials to some extent. Therefore, it was greatly to be regretted that College Dons twisted their heads round so that they looked backwards over their shoulders; they should remember that when Orpheus did that he lost Eurydice.

MR S. C. COCKERELL, referring to the remarks made by the author and Mr. Powys about the work of William Morris in Cambridge, said the work ascribed to Morris was not his work only but the co-operative work of Morris, Philip Webb, who did a considerable amount of work in Cambridge in the way of window designing, Burne-Jones, Madox Brown and Rossetti. They did work together in Queens' College and Peterhouse, and Burne-Jones, Madox Brown and Rossetti worked in Jesus College. A great deal of the decoration in All Saints' Church might be called Morris', but it was really an example of the very early work of the firm. It was co-operative work. Morris was no more concerned in it than others—perhaps less so—except that he conducted the business side of the firm. There was not very much decoration in the church, but the main east window was very interesting, because it had some cartoons by Morris, some by Burne-Jones and some by Madox Brown, and it was known to very few people which were which. He happened to have a copy of a chart which showed that

MR. JOHN SLATER, F.R.I.B.A., in proposing a vote of thanks to Mr. Lyon for his extremely interesting paper and particularly for the beautiful slides he had shown of the Cambridge buildings, said the author suggested that the modern architects who had designed buildings in Cambridge had perhaps hardly done justice to themselves. Might not it be that they were so overwhelmed by the traditions of the place that they really had not been themselves in the work they had done? Mr. Ricardo had mentioned the well-known fact that fashions changed in architecture from generation to generation. One of the most striking instances of that occurred in the preface to a book written by Quatremere de Quincy on the lives of the most celebrated architects, where he said: "There be found in this volume not a single word about that style of architecture which is called Gothic, for we maintain that no architecture is worthy of the name that does not depend upon the

principles and the motives of Greece and Rome." That was written by a man who had within his view all the glorious Gothic cathedrals of France, and yet he could see no beauty in them at all. He thought everyone would agree with the author as to the undesirability of erecting buildings in Cambridge without any definite plan, dotting them about here and there, for there could be no doubt that much of the beauty of the old buildings in Cambridge and in Oxford lay in the magnificent quadrangles round which they grew.

The resolution of thanks was carried unanimously.

Mr. T. H. LYON, in reply, said that with reference to Mr Ricardo's remarks he did not suggest that the whole of Caius College should be pulled down; he was only referring to the tower of the building.

The meeting then terminated.

CORRESPONDENCE.

INDUSTRIAL FATIGUE RESEARCH.

As Chairman of an Advisory Committee which has concerned itself with the "Care and Settlement of Subnormal Workers (ex-Service men) in Rural Industries," I should like to make a short statement on this subject, which must be intimately connected with the work of the Industrial Fatigue Research Board. The scheme of our Committee was to establish what has long been known on the Continent as middle and minor industry, in the rural districts of England, by means of small workshops, under a co-operative system. We have had in mind the large class of subnormal, or substandard, workers, injured in war, who are not always able to work six days a week and eight hours a day, and who—we have reason to think—will find a permanent settlement and occupation in lesser industries of this character.

Most important experience has now been gained in the Training Centres during the last few years, especially as regards partially disabled men. I understand that these men are no longer now received for training in ordinary trades, but that a new policy is to be adopted. Suitable minor and middle industries, both congenial and lucrative, and hitherto mainly carried on abroad, are now likely to be established in country districts throughout England for these men.

This being so, it seems important to consider what are the conditions under which such men can be trained and settled in such occupations with any prospect of success. As a result of considerable personal experience, I should like to offer four propositions:—

- (1) *Regulation of Work.* That it is necessary for the success of reduced workers in rural industry, that the amount and nature of work done by each man shall be definitely prescribed, with due regard to his physical and mental condition from time to time.
- (2) *Measurements, Records and Research.* That an approved and uniform procedure be adopted for measuring and recording each man's condition. In the case of subnormal and injured men the periodical observations should include:—
 - (a) Condition of limbs (Arthrometry).
 - (b) Condition of muscular power (Dynamometry).
 - (c) Breathing Capacity (Spirometry).
 - (d) Mental power and reactions (Psychometry).

A register of the capacity and fitness of all workers should be kept, and records made every three months.

- (3) *Visiting Medical Staff.* As small industries will be widely scattered, and the workers will not be concentrated in large aggregations, it seems advisable that the necessary examinations and records should be undertaken by a small skilled visiting staff.
- (4) *Treatment.* The remarkable success which has attended the large number of clinics established by the Government for out-patient treatment suggests the advisability of adopting the same principle for subnormal workers in minor industries and on the land, throughout the country. It has been clearly demonstrated that medical oversight of this kind greatly promotes the fitness of the workers, and increases their economic value.

R. FORTESCUE FOX, M.D.

AFRICAN OIL PALM IN MALAYA.

According to a report by the United States Vice-Consul at Singapore, the Government of Perak, one of the Federated Malay States, is prepared to grant land, upon very favourable terms, for the cultivation of the African oil palm. At present the chief countries of origin of this palm and oil are Southern Nigeria, the Gold Coast, Sierra Leone, the French Ivory Coast, and Kongo.

The Department of Agriculture of the local Government and the managers of several rubber plantations have been conducting experiments, and have found that the soil and climate of Malaya are so well adapted to this tree that its oil content is equal to those grown in South Africa. It is thought that as Malaya has the advantages of available labour and facilities for transportation, the cultivation of this palm could be carried on most successfully.

The oil is used mainly in the manufacture of butter substitutes and soap, and has proved valuable for such purposes. It is presumed

that its use would be similar to that of the coconut, the meat of which was in 1909 ground and mixed and placed upon the market as "Palmira" by a German firm in Mannheim. This was a hard, snow-white vegetable cooking fat, and when mixed with the yolk of an egg and water made a very good substitute for butter.

The Government is clearing 50,000 acres of land for oil-palm plantations, which in itself means an increased demand for tractors, stump pullers, portable saw machinery, ploughs, vegetable-oil mill machinery, and kindred equipment.

Perak is on the west coast of the Malay Peninsula and has an estimated area of 7,875 square miles. The State is well watered by numerous streams and rivers. The Perak River, the most important stream, is navigable for about 40 miles from its mouth by small steamers of 300 to 400 tons burden, and thence navigable for another 100 miles by cargo boats. There is no true rainy season, but the wettest months are October, November, and December. In the Krian district the Government has completed an extensive and costly irrigation scheme, and large areas are under rice, sugar, and rubber. The Chinese and the Tamil natives of India form the great bulk of the labour force of the State.

In addition to over 880 miles of metalled roads and a great number of other roads, the Federated Malay States Railway runs from Port Buntar to Tanjong Malim, the entire length of Perak, and is connected with the coasts and interior by means of branch lines.

BRISTLE INDUSTRY IN POLAND.

Before the war statistics recorded a total of 5,812,000 hogs in the territory now comprising the Republic of Poland. The number of hogs since the war has diminished considerably, but is now on the increase, and Polish dealers expect a normal production of 5,812,000 pounds of bristles per year to be possible in the near future. On the average a hog gives 1 pound of bristles.

The better grades of Polish bristles were exported. For local consumption the Polish manufacturers were accustomed to use the Russian bristle, which is stiffer. The Polish bristle is of the best technical quality, being long and elastic.

Leipzig was formerly the heaviest buyer of Polish and Russian bristles. The tendency at present, writes the U.S. Trade Commissioner at Warsaw, is for Warsaw not only to clean and assort the bristles as before the war, but to replace Leipzig in importance for the direct exportation to the United States, France, and the United Kingdom. Recently a corporation known as Ostoje was organized in Warsaw to engage in this business.

KAURI GUM INDUSTRY IN NEW ZEALAND.

The kauri-gum industry, which has been an important factor in and around Auckland for half a century, is taking on new impetus since the closing of the war. In the past most of the work was done by hand and by individuals. Something like gold was mined years ago in new fields, with the result that the top had only been skimmed over and the better pockets dug out. These methods have secured about £20,000,000 of kauri gum to date, and it is claimed that there is still left in the kauri fields gum and by-products worth at least two or three times what has been taken out.

Until recently the development of the kauri gum fields has been left entirely to private enterprise, but about three years ago the New Zealand Government established a department for the supervision and encouragement of the industry, with the result that more extensive operations are being undertaken by companies as well as by individuals. It is now proposed, writes the U.S. Consul-General at Auckland, to develop the industry along more systematic and scientific lines than those hitherto employed.

From twelve to fifteen thousand tons of kauri gum will, it is expected, be produced per annum, instead of eight or nine thousand tons, as was the case previous to the war, to say nothing of the by-products, which are estimated to be worth as much as, or more than, the gum itself. One company anticipates an output of eight to nine thousand tons of gum per annum and there are besides many private individuals at work in different sections of the field, and other interests are contemplating putting in new up-to-date plants.

The latest undertaking is to gather the gum mechanically from the peat, or pukau, which is really the damaged kauri gum in the low or swampy land found in the territory around Auckland. This is to be worked by what is known as the sluice process, similar to sluicing for gold. The peat is placed on a screen and water forced through it. The screen gathers the chip gum and allows the waste or tailings to drop beneath. This chipped gum is divided into about 15 per cent first quality, 15 per cent second quality, and 70 per cent low grade. The tailings are converted into kauri-gum oil in a manner similar to extracting oil from shale. It is estimated that 40 to 50 gallons of kauri-gum oil can be taken from a cubic yard of pukau. This oil is a very valuable commercial oil, containing a large percentage of motor spirit and turpentine.

It is stated that one company in Auckland has control of kauri-gum rights covering 47,000 acres, estimated to contain 13,000,000 cubic yards of pukau. In addition, the New Zealand Government still holds kauri-gum reservations that are estimated to contain an even larger quantity of pukau, to say nothing of many private interests holding small sections of kauri

swamps. This will give some idea of the real size of the industry that means so much to the paint and varnish industries, as well as to the linoleum and rubber manufacturers.

The New Zealand Government is allowing persons to stake out tracts or claims of three acres on the Government reservations, for which the individual operators must pay 10 per cent. of the value of the gum taken from these swamps. It is said that a large number of claims are being staked out.

In addition to the gum and oil that can be extracted from the pukau, there are large numbers of buried kauri trees, from which great quantities of oil can very easily be extracted by a process similar to that used in extracting turpentine from pine logs.

GENERAL NOTE

INDIAN LABOUR FOR BRITISH GUIANA—The visit paid to India some two years ago by representatives of British Guiana in connection with the Indian Immigration question seems to be having good results. The Government at Georgetown having promised to introduce a legislative measure conferring equal political rights on Indian Colonists, the Government of India is despatching a deputation to British Guiana to investigate the local conditions and to ascertain whether further guarantees affecting the status of Indians are necessary. The deputation consists of Mr. G. F. Keatinge, I.C.S., and two native Indian gentlemen, one of whom is Deputy President of the Madras Legislative Council and the other is prominently identified with the "Servants of India." The singular emptiness of British Guiana, a fertile land as large as Great Britain, with a cultivated area only one-fifth the size of Kent, was well brought out by Sir Walter Egerton in the paper on "British Guiana and the Problem of its Development," read by him before the Dominions and Colonies Section of the Society in 1918. He compared the population with that of some of our other tropical colonies. The population of the British West Indies in one-eighth the area was, three years ago, 1,800,000—six times that of British Guiana; in Ceylon, 1,500,000 British Guiana, three and a half times as large, has only one-fifteenth of Ceylon's total. The Straits Settlements and Federated Malay States boasted a population of 2,000,000.

*MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.

MONDAY, DECEMBER 5.. Farmers' Club, at the Surveyors' Institute, 12, Great George Street, S.W., 6 p.m. Annual General Meeting. Dr. M. J. Rowlands, "Scientific Pig Keeping, and its Relation to Vitamins." Geographical Society, 135, New Bond Street, W., 8.30 p.m. Mr. G. M. Gathorne-Hardy, "A Recent Journey in Northern Labrador." Chemical Industry, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. W. L. Baillie, "An autoclave Test for the Grading of Chemical Glassware." 2. Dr. E.

Fyleman, "Separation of Adherent Oil or Bitumen from Rock."

TUESDAY, DECEMBER 6.. Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. H. M. Edmonds, "A New Mode of Producing Sculptures by the Aid of Photography." Metals, Institute of (Birmingham Local Section), at the Chamber of Commerce, New Street, Birmingham, 7.30 p.m. Mr. G. W. Mullins, "The Early History of Copper and Bronze."

WEDNESDAY, DECEMBER 7.. Geological Society, Burlington House, W., 5.30 p.m.

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. J. Baker, "Some Problems of Unemployment."

Book-keepers, Institute of, at the Haberdashers' Hall, Gresham Street, E.C., 6.30 p.m. Mr. R. N. Carter, "An Introduction to the Study of Income Tax."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. (Wireless Section). Mr. T. L. Eckerley, "An Investigation of Transmitting Aerial Resistances."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. B. S. Evans, "The Estimation of Small Quantities of Antimony in Copper and Brass." 2. Mr. A. Lucas, "The Inks of Ancient and Modern Egypt." 3. Mr. C. L. Claremont, "Notes on the analysis and use of Red Squill in Rat Poisons."

United Service Institution, Whitehall, S.W., 2.30 p.m. Lt.-Col. W. D. Croft, "The Influence of Tanks upon Tactics."

University of London, South Kensington, S.W., 5 p.m. Sir Frederick Bridge, "Sir W. Leighton's Great Collection of Early 17th Century Motets by Eminent English Composers." (Lecture II)

African Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 4.30 p.m.

THURSDAY, DECEMBER 8.. Fine Art Trade Guild, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7 p.m.

University of London, at the Imperial College of Science, South Kensington, S.W., 5.30 p.m. Mr. W. Bateson, "Recent Advances in Genetics." (Lecture VI.)

Garden Cities and Town Planning Association, King's College, Strand, W.C., 5.30 p.m. Lecture on "The City of Milan."

Camera Club, 17, John Street, Adelphi, W.C., 8.15 p.m. Captain H. Lambert, "The Intricacies of the Silent Drama and its Making."

Historical Society, 22, Russell Square, W.C., 5 p.m. Mr. H. G. Richards, "Year Books and Plea Rolls as Sources of Historical Information."

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Optical Society, at the Imperial College of Science, South Kensington, S.W., 7.30 p.m.

Mechanical Engineers, Institution of (Midland Branch), The University, Edmund Street, Birmingham, 7.30 p.m. Mr. C. V. A. Eley, "The Turbine Furnace."

Metals, Institute of, Cannon Street Hotel, E.C., 8 p.m. (Joint Meeting with Institution of British Foundrymen) Mr. S. A. E. Wells, "Casting in Metal Moulds."

FRIDAY, DECEMBER 9.. London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 4.30 p.m. Mr. C. H. Grinling, "The Heights Around London."

Japan Society, 20, Hanover Square, W., 5 p.m. Mr. W. L. Schwartz, "The Potters and Pottery of Satsuma."

Astronomical Society, Burlington House, W., 5 p.m.

Electrical Engineers, Institution of (Irish Centre), Royal College of Science, Dublin, 8 p.m. Mr. F. E. Walker, "Electrical Vehicles; their Design, Construction and Potentialities."

Malacological Society, at the Linnean Society, Burlington House, W.

Physical Society, at the Imperial College of Science, South Kensington, W., 5 p.m.

Engineers, Junior Institution of, at the Royal United Service Institution, Whitehall, S.W., 7.30 p.m. Presidential Address by Mr. C. H. Wordingham.

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday of the week preceding the Meeting.

No. 3,603.

VOL. LXX.

FRIDAY, DECEMBER 9, 1921

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 12th, at 8 p.m.
(Cantor Lecture.) ARTHUR M. HIND,
O.B.E., M.A., Assistant-Keeper, Department of Prints and Drawings, British Museum, and Slade Professor of Fine Art in the University of Oxford, "Processes of Engraving and Etching." (Lecture III.)

WEDNESDAY, DECEMBER 14th, at 8 p.m.
(Ordinary Meeting.) SIR WALTER BEAUPRÉ TOWNLEY, K.C.M.G., Minister to the Netherlands, 1917-19, "Trade with the Netherlands East Indies." THE RIGHT HON. LORD EMMOTT, G.C.M.G., G.B.E., in the chair.

Further particulars of the Society's meetings will be found at the end of this number.

FIFTH ORDINARY MEETING

WEDNESDAY, NOVEMBER 30th; SIR FRANK BAINES, C.B.E., M.V.O., Director of Works, H.M. Office of Works and Public Buildings, in the Chair.

The following candidate was proposed for election as a Fellow of the Society:

L. D. Varshnei, Bahjoi, India

The following candidates were balloted for and duly elected Fellows of the Society:—
Blagg, Percy, London.

Elton-Bott, John Richard, Burma.

Ross, Alexander G., Fiji.

Sanders, Marion Eugénie, London

Wright, Hugh Francis, New Barnet, Herts.

A paper on "The Preservation of Stone" was read by MR. NOEL HEATON, B.Sc.

The paper and discussion will be published in the *Journal* of December 30th.

CANTOR LECTURES.

On Monday evening, December 5th, MR. ARTHUR M. HIND, O.B.E., M.A., Slade Professor of Fine Art in the University of

Oxford, delivered the second lecture of his course on "Processes of Engraving and Etching."

The lectures will be published later on in the *Journal*.

DOMINIONS AND COLONIES SECTIONS.

TUESDAY, DECEMBER 6th; THE DUKE OF DEVONSHIRE, K.G., G.C.M.G., G.C.V.O., in the chair. A paper on "British Columbia—The Awakening of the Pacific" was read by MR. FREDERICK WADE, B.A., K.C., Agent-General for British Columbia.

The paper and discussion will be published in the *Journal* of January 6th.

MANN JUVENILE LECTURES.

Under the Mann Trust a short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, 4th and 11th January, 1922, at 3 p.m., by Mr. William Reginald Ormandy, D.Sc., F.I.C., on "Clay: What it is—Where it comes from—and What can be done with it." The lectures will be illustrated with experiments.

Special tickets are required for these lectures. A sufficient number to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply to the Secretary at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

WEDNESDAY, NOVEMBER 23RD, 1921.

MR. ALAN A. CAMPBELL SWINTON, F.R.S.,
Chairman of the Council, in the Chair.

THE CHAIRMAN, in opening the meeting, said that the Lecture about to be delivered by Prof. Fleming was a "Trueman Wood" Lecture, i.e., one of the Lectures that had been instituted by the Society in commemoration of the 42 or 43 years that Sir Henry Trueman Wood had passed in the service of the Society. It had been hoped that Sir Henry would have been able to attend the meeting, but unfortunately he was not able to do so. He thought he was right in saying that Professor Fleming had given more Lectures in the Hall of the Royal Society of Arts than any other living person. He had been associated with Senatore Marconi and with the Marconi Company for many years and had written most comprehensive books on the subject of wireless telegraphy, and there was no one more competent to deliver a Lecture on the coming of age of long distance wireless telegraphy.

THE COMING OF AGE OF LONG DISTANCE RADIOTELEGRAPHY AND SOME OF ITS SCIENTIFIC PROBLEMS.

By J. A. FLEMING, M.A., D.Sc., F.R.S.,
Albert Medalist of the Royal Society of Arts.

FIFTH TRUEMAN WOOD LECTURE.

I. HISTORICAL.

1. Almost exactly 21 years ago a small building had been erected in a lonely spot on the coast of Cornwall, called Poldhu, at the extreme West of England, and was being equipped with machinery for an experiment of transcendent interest. (See Fig. 1.)

Senatore Marconi had during four years previously given innumerable demonstrations of the utility of the apparatus he had devised for transmitting intelligence by electromagnetic waves over land and sea, and had telegraphically covered distances up to about 100 miles. These achievements stimulated in him a desire to try for greater things, and to attempt to fling electric wave signals across the Atlantic Ocean. Although

FIG. 1.—First Building erected at Poldhu, Cornwall, England, for long distance wireless telegraphy in the autumn of 1900, by Marconi's Wireless Telegraph Company, Ltd

more cautious pioneers might have hesitated to take the leap from 100 miles to 2,100 miles in one step, yet with characteristic courage he decided to attack the problem of long-distance radiotelegraphy without delay. The curious thing is that all of us, inventors and scientists alike, were then completely in ignorance of the secret arrangements made in Nature for facilitating and also for hindering these ambitious schemes. To some of these we shall presently refer.

The first question was that of power. Up until then only a 10-inch spark coil actuated by a dozen storage cells had been employed for the transmitter, using perhaps 150 watts and radiating may be 5 or 10 watts from the aerial.

The conversion of this laboratory apparatus into engineering plant had to proceed tentatively in the absence of all previous experience, but part of the duty of specifying for it having been laid upon your lecturer, he recommended for this initial attempt a 32-h.p. Hornsby-Ackroyd oil engine driving a 25 k.w. Mather and Platt 50-cycle alternator providing current for two 20 k.w. Berry transformers, stepping up voltage from 2,000 to 20,000. Six months previously Mr. Marconi had applied for a patent, No. 7,777, of April 26th, 1900, for a noteworthy modification of his original system in which electric oscillations produced by the discharge of a battery of Leyden jars through one coil of a transformer were made to induce syntonic oscillations in the aerial connected to its secondary circuit, and at the receiving end the oscillations picked up by the receiving aerial were caused to create others in a tuned closed condenser circuit. This important patent was subsequently upheld in litigation as a fundamental invention, and it carried to their logical issue and gave practical form to the recommendations made in a prior British patent by Sir Oliver Lodge (No. 11,575 of 1897) as to the necessity for syntonic agreement between sending and receiving stations and the advantage of using feebly damped waves.

This system was described by Senatore Marconi to the Royal Society of Arts in a paper read on May 15th, 1901, entitled "Syntonic Wireless Telegraphy." (1) The actual arrangements first made at Poldhu comprised a modification of this syntonic system in which a double transformation

with two spark gaps and two sets of condensers were employed as described in British Specifications Nos. 20,576 and 22,126, of 1900, and No. 3,481, of 1901, granted to me.

This large scale work necessitated the design of a durable form of condenser less bulky than Leyden jars, and they were constructed by placing 20 glass plates 16 inches square coated on each side with a square foot of tinfoil in stoneware boxes filled up with linseed oil. Each box had a capacity of $\frac{1}{8}$ of a microfarad.

The signals were made by short circuiting choking coils inserted in the alternator circuit on the low tension side of the transformers. The earliest troubles occurred with the spark balls, owing to the production of an arc discharge by the transformer. Some of these difficulties were minimised by the use of dischargers made with two massive iron discs kept in slow rotation by electric motors and the use of an air blast, but not finally overcome until Senatore Marconi invented his high speed rotating studded disc dischargers in which the arc discharge was blown out by the blast of air due to rotation, but the condenser oscillating discharge remained. It should be noted that the discharge so produced is quenched and consists only of two or three oscillations. This, however, is a great advantage, as it prevents the back transfer of energy from the aerial and prolongs the oscillations produced in it. These dischargers also greatly increased the possible speed of signalling.

2. The general arrangements used in the plant with which the first radio signals were

FIG. 2.—Circuits of first spark transmitter used at Poldhu, 1901.

A, aerial; C₁, C₂, Condensers; S₁, S₂, Spark balls; J₁, J₂, Jiggers; T₁, T₂, Step-up Transformers; Ch₁, Ch₂, Chokers; K₁, K₂, Keys; D, Alternator; B, Storage battery; E, Earth.

(1) See *Journal of the Royal Society of Arts*, May 17th, 1901 Vol. 49, p. 505.

thrown across the Atlantic in December, 1901, were as follows:—

The alternator D (see Fig. 2) was driven by the oil engine at a speed which gave about 45 cycles per second, and its low frequency voltage of about 450-600 was stepped up by two transformers T_1 T_2 in parallel, choking coils Ch_1 and Ch_2 were inserted, which cut down the primary current unless they were short-circuited by keys. The high tension voltage of the transformers was used to charge a condenser C_1 of 1.43 mfd. capacity, and this was discharged across the 7.5 mm. spark gap S_1 . Other coils, W, were inserted to tune the condenser to the low frequency transformer circuit. The oscillatory current was passed through a transformer J_1 , having a step-up voltage ratio of 1 : 10, and this in turn charged a condenser C_2 of 1/27th mfd. capacity which discharged across a 40 mm. spark gap S_2 . These last oscillations were inductively transferred to the aerial by an oscillation transformer J_2 with ratio of 1 : 10. The aerial consisted of 54 7/20 copper wires arranged fan-shape and upheld by a triatic stay between two masts 150 feet high. The current into this aerial measured at the base was about 17 amperes. Its capacity was probably not far from 0.003 mfd. The wave length (not measured) was perhaps about 1,000 metres.

3. This plant was completed and tested for short-distance working during 1901, and Mr. Marconi left England on November 27th, 1901, in the *s.s. Sardinian*, taking with him his assistants, Mr. Kemp and Mr. Paget, and also a number of balloons and kites. His intention was to elevate a temporary receiving aerial in Newfoundland and endeavour to detect the signals sent according to a plan from Poldhu. On arriving at St. John's in Newfoundland, he secured the kind co-operation of the Governor, Sir Cavendish Boyle, and the Premier, Sir Robert Bond, and found a suitable station in a Government building on Signal Hill. He sent word for the signalling to begin at Poldhu, sending the letter S (three dots) at certain hours. After some difficulties in elevating his kites and wires, he was able on Thursday, December 12th, 1901, to state that he had certainly received signals from Poldhu, detected by a suitable coherer and telephone in Newfoundland, and on December 14th, 1901, he cabled this information to England. The actual power used in driving the

alternator was not above 10 or 12 h.p., but, of course, a mere fraction of this was radiated in the form of electric waves.

These profoundly interesting experiments were, however, brought to an end by the Anglo-American Telegraph Company, who had a monopoly of receiving in Newfoundland transatlantic messages until April, 1904, and they entered a demand for this research work to cease. Nevertheless, enough had been done to show that transatlantic radiotelegraphy was not an impossibility, but fully practicable with suitable arrangements.

It was, at any rate, enough to obtain for Senatore Marconi the necessary support to erect permanent masts and aerials and transmitters both at Glace Bay, Nova Scotia, and at Cape Cod, Mass., U.S.A., and a year later, on December 21st, 1902, he was able to dispatch wireless messages across the Atlantic which made long-distance radiotelegraphy a demonstrated achievement.

4. Much, however, remained to be accomplished before transatlantic radiotelegraphy could reach a commercial stage. For one thing, experience had shown the necessity for much larger power in the aerial, and it was considered advisable to establish first two new permanent stations: one at Clifden, in Connemara, Ireland, and the other at Glace Bay, Nova Scotia. These stations were sufficiently advanced by the middle of 1907 to admit of telegraphic work being undertaken, and a limited service of press-messages was inaugurated. But a disastrous fire at the Glace Bay Station in August, 1909, caused delay, and it was not until April, 1910, that regular communication between these stations for public use was re-established. Meanwhile, however, even in 1907 it had been demonstrated that the demands for accuracy and speed could be fulfilled by a wireless transatlantic service.

II. SPARK SYSTEMS.

5. It is impossible to follow out in detail here all the changes which were made in the working plant of these pioneer long-distance stations between 1902 and 1910. Suffice it to say that an early improvement in the arrangements at Poldhu consisted in increasing the group frequency of the spark discharges, which was necessitated by the introduction of the telephonic method of reception and the invention of his beautiful magnetic detector by Marconi in 1902.

The low frequency alternator was replaced by one having a frequency of 200 or more so as to raise the pitch of the note heard in the telephone, which is that of the spark frequency, and make it more easily distinguishable above the sounds due to atmospheric disturbances. Also the oil engine was replaced by a steam engine to give more uniform turning movement. This improvement was carried still further in the first arrangements at Clifden. The alternator and transformers were abolished and a battery of 6,000 small storage cells was kept charged by a number of high voltage direct current dynamos run in series. These cells kept a large air condenser charged and this was discharged through the primary coil of an oscillation transformer, the secondary circuit being in connection with the aerial and the earth. This condenser had a capacity of two mids. and was formed of large iron plates hung 12 inches apart. It had, therefore, negligible energy loss. The discharges were made at the rate of 500 or 600 per second by a studded disc rotating discharger. Any are formed was extinguished at once, but the feebly damped oscillations survived and produced in the telephone at the receiving end a high musical note more easily read above the sounds of the atmospherics. Investigations had shown by that time the advantages of increased wave length for long-distance working, and it was raised to 5,000 or 7,000 metres in the early work at Clifden and Glace Bay. It is probably not necessary to refer here at length to other types of intermittent spark generators of electric waves such as the Quenched Spark devised later on, since, although these have still a field of utility for short or moderate distance working, the continuous wave system has proved to have such incontestable advantages for long distances that no one would at the present date propose to equip a long range high power station on the intermittent spark discharge system.

6. The Timed Spark generator forms, however, the connecting link between the true spark systems and the continuous wave generators. It was developed by Senatore Marconi as an application of his high speed rotating dischargers before any of the other present-day methods of creating powerful continuous oscillations had arrived at maturity. This method of generating powerful undamped oscillations in an aerial wave produced by the free discharges of

condensers was adopted in the large Marconi stations at Carnarvon, N. Wales, England, and New Jersey, U.S.A., and Stavanger, in Norway, which were completed just before the great war in 1914 and intended for public transatlantic telegraph service. In this system two large batteries of condensers are kept charged by direct current dynamos producing current at 5,000 to 10,000 volts or so. These condensers are discharged alternately through the primary coils of transformers, the secondaries of which are in series with the aerial and earth. The discharge is effected by two studded disc dischargers driven by a motor and keyed to the same shaft, but with fixed electrodes so placed that the condensers are discharged in such fashion that the discharge of one condenser begins just before the oscillations produced by the other condenser finish. In order to produce exact continuity and join up the groups of oscillations in the aerial in step, the discharges are regulated by a timing or trigger disc. The studs on the revolving discharges are set just so far away from the fixed contacts that the main condensers cannot discharge across until the air in the gap is ionised by a small pilot spark. This is provided by the timing discharger just at the right intervals, and the result is to create in the aerial a practically undamped oscillation with slight fluctuations of amplitude at regular intervals. The signalling is conducted by interrupting the charging current (about 0.5 ampere) of the small condenser in the timing disc circuit so that the manipulation of a very small amount of power, perhaps a few watts, controls a radiation of a hundred kilowatts or more from the aerial.

7. In connection with these pre-war long-distance stations of the Marconi Company, two inventions of Senatore Marconi are noteworthy, viz., the inverted L directive aerial and a simple yet very practical method of duplex transmission and reception.⁽²⁾ This last is achieved by the plan of separating the receiving station from the transmitting by some miles. In the case of Carnarvon, the receiving station is at Towyn on the coast of Wales, 60 miles away. At the latter there are two aerials, one large for distant reception, and one small balancing aerial placed in a particular position, the function of which is to neutralize on the receiving circuits the effects of the powerful

(2) See British Patent Specification. G. Marconi; No. 14788 of 1905.

waves from the near-by transmitter, whilst not much neutralizing the feeble waves coming from the distant transmitter.

The sending aërials in these large spark stations are enormous structures supported on ten steel masts 400 feet high upholding an antenna of multiple horizontal wires about 3,000 feet long and 400 feet above the ground. The earth plate system is also co-extensive with it. The radiated wave length is about 14,000 metres or nearly 10 miles, but the natural wave length of the aerial alone is 5,600 metres.

The signalling can be done locally in the Carnarvon station or it can be controlled from the Towyn receiving station, and even by means of Creed perforators automatically conducted by the ordinary telegraphic line currents dispatched from London.

It is now generally the custom to separate the receiving station from the home transmitting station by a distance of several miles and to receive on frame aërials placed in the right position as regards the distant transmitting station.

III. THE ARC OSCILLATION GENERATOR.

8. We must then return in point of time to our starting point in 1900 and glance at other collateral inventions in connection with long-distance radiotelegraphy which developed alongside of the spark-discharge system. In that year the late Mr. Duddell described a new method of creating electric oscillations by shunting a direct-current arc, formed between solid carbons, by an inductance and condensers in series.⁽³⁾ With the ordinary carbon arc in air it was necessary to employ rather a large capacity, viz., 1 to 5 mfd., and an inductance of about 5 millihenrys to obtain oscillations of any vigour in the shunt circuit, and hence their frequency was necessarily low and far too low to be of use in radiotelegraphy.

The phenomenon is essentially dependent upon the fact that for such an arc the characteristic curve of electrode potential difference in terms of arc current is a downward sloping curve.

Even after all the research on this so-called musical arc the exact reasons for this negative slope of the characteristic are not absolutely determined.

The arc discharge consists in the continual ionisation of the carbon vapour with resulting movement of heavy positive ions

towards the cathode and negative electrons towards the anode. The ionic bombardment of the electrodes keeps up their temperature and the supply of vapour. There is probably also an accumulation of negative ions round the positive carbon tip and of positive ions round the negative carbon, and these create that steep drop in potential which exists near the electrodes. It is well known that a gaseous conductor does not obey Ohm's law; that is, the conductivity is not constant and independent of the current. The conductivity of an ionised gas depends upon the number of ions present per unit volume and upon the velocity which these can acquire under unit electric force.

If the current through a gas increases, this means that the velocity of the ions increases, and this may result in an increased production of ions by collision of the moving ions with molecules. Hence under certain conditions the conductivity increases faster than the current, and therefore the product of current and instantaneous resistance decreases. But this last product is a measure of the potential difference of the electrodes. This takes place in the electric arc. Accordingly, an increase of current through the arc is accompanied by a decrease of potential of the carbon electrodes, as experiment shows.

The increase of conductivity over that of the current no doubt chiefly takes place in the layers of carbon vapour close to the electrodes, because there the electric force is largest and the ions have their greatest velocity. Experience shows that it takes place most effectively with short arcs when formed in air between carbon electrodes.

It is also most pronounced with small arc current density, as with large currents any additional ionisation by collision becomes less important. This is clearly shown by the increase of slope of the current-voltage characteristic curve with decrease in the arc current.

If the arc is being formed between solid carbons in air, then, owing to the interpenetration of the carbon vapour by oxygen atoms and the affinity of these for negative electrons forming negative oxygen ions, there is an action tending to deplete the arc of ions which keeps down the rate of increase of conductivity with current. Hence the characteristic curve then never has a very steep downward slope.

If, however, the arc is surrounded and

⁽³⁾ See W. Duddell. *Journ. Inst. Elec. Eng.; Lond.* Vol. 30, p. 232. 1900.

interpenetrated by hydrogen, then this depletion does not occur, and, on the contrary, the ions obtain a greater mobility which facilitates further ionisation by collision.

Hence the effect of forming the arc in a hydrogen atmosphere is to steepen the slope of the characteristic curve for given currents, as shown by the experiments of Upson. In place of hydrogen we can use alcohol vapour, petrol, or coal gas with the same result. As a result of the increased steepness of the characteristic curve we are able to obtain oscillations of considerable energy when using a shunt condenser of rather small capacity, and hence create oscillations of much higher frequency than when using a carbon arc in air.

The discovery of this fact by V. Poulsen, in 1903, formed the starting-point for fresh important developments in radiotelegraphy. By the employment of a powerful transverse magnetic field of a certain optimum strength, Poulsen found that the arc current could be just extinguished at each oscillation, but would re-light itself if the negative electrode was formed of a carbon rod and remained hot. In this case the R.M.S. value of the alternating current through the condenser may be as much as 70% ($=1/\sqrt{2}$) of the direct current supplied to the arc. We have therefore three currents to consider:

(1) The condenser current (i_c), which is not a purely sinusoidal current, but at least has a principal constituent which is a simple harmonic current.

(2) The supply current, I_d , which is a purely direct current, and

(3) The arc current, i_a , which is the sum of I_d and i_c .

If we may, as a first approximation, assume that $i_c = I_c \sin pt$, then in the case of the optimum magnetic field, $I_c = I_d$. $\therefore i_a = I_d (1 + \sin pt)$. The R.M.S. value of i_a (I_a) is then $I_d \sqrt{2}$ and $I_d = (I_a) \sqrt{2}$. Hence $I_c = (I_a) \sqrt{2}$ and $I_d = (I_a) \sqrt{2}$. We can therefore represent the R.M.S. values in the optimum case, of the arc current, the shunt current, and the direct current by the sides of a right-angled triangle whose lengths are respectively $\sqrt{3}$, 1, and $\sqrt{2}$.

The optimum magnetic field H_0 which produces this result depends on the frequency of the oscillations. If λ is the wave length, then, according to P. O. Pedersen⁽⁴⁾, $H_0 =$

$$\frac{a}{\lambda} - b \text{ where } a \text{ and } b \text{ are constants. L. F.}$$

Fuller gives the formula $H_0 = K \sqrt{P/\lambda}$ where P is the power given to the arc and K depends upon the vapour or gas in which it is formed. K is larger for alcohol than for kerosene vapour. The optimum field is smaller in the case of hydrogen, because the high molecular velocity assists dis-ionisation, and since kerosene and volatile hydrocarbons dissociate into hydrogen and solid carbon whilst alcohol furnishes carbon dioxide, hydrogen and carbon, it follows that the optimum field with alcohol must be stronger than for kerosene or petrol vapour. For a power of 50 K.W. and wave lengths of 7,000 metres the arc in alcohol vapour requires a magnetic field of 8,300 C.G.S. units. For a power of 1,000 K.W. and a wave length of 20,000 metres the field must be 13,500 C.G.S.

Since, however, the iron pole pieces must be kept out of the arc, the air gap is necessarily large, and hence the ampere-turns put on the iron core of the magnet must be large. Thus for large powers the arc generator requires very massive electro-magnets and some have been constructed weighing even 80 tons. Great attention has to be paid to the form of the pole pieces.

Transmitting plant on this system consists, therefore, of one or more dynamos capable of supplying direct current at 500-600 volts or more with which arcs are formed between a thick carbon (—) and water-cooled copper (+) electrodes in a chamber kept full of alcohol or kerosene vapour. A powerful magnetic field is maintained transversely to the arc sometimes by the arc currents itself or preferably by a separate dynamo. The arc is shunted by a condenser and inductance, a portion of which latter coil may be in series with the aerial. Signalling is conducted generally by throwing the aerial out of tune with the condenser shunt circuit.

9. There are two restrictive qualities of this arc generator which must be noted. First, the alternating current in the condenser circuit is not of pure sine wave form, and this gives rise to the radiation of other wave lengths besides the fundamental.

In the next place, the efficiency of conversion, even at best, is not high. All those cases of energy transformation in which production of heat is necessary to the transformation have a low efficiency, as, for instance, electric lamps, 5 to 15% thermo-

(4) P. O. Pedersen. *Proc. Inst. Radio Eng.* U.S.A. Vol. 5, p. 256. August, 1917.

pilos, etc. If we denote by C the direct current supplied to the arc and by V the potential difference of the carbons, then CV watts is the power given to the arc, neglecting the drop in the regulating resistances. If A is the condenser shunt current and R is the shunt circuit resistance (including radiation resistance), then A^2R is the power given out as alternating current. But with optimum field we may have $A\sqrt{2}=C$ or $\frac{1}{2}C^2R$ is the high frequency power. Then the efficiency $e = \frac{1}{2} \frac{CR}{V}$.

If we denote the direct current resistance of the arc by R_d , then $R_d = \frac{V}{C}$ or $e = \frac{1}{2}R/R_d$.

Now R_d is nearly always greater than R , and hence the efficiency can at best approximate to 50%, and is generally less. One other disadvantage must be noted which, however, is, I believe, being overcome, viz., that the power continues to be expended on the arc whether signals are being sent or spaces, as the arc cannot be extinguished and re-lit suddenly.

Nevertheless, the fact remains that the arc method of wave generation has been very extensively used in the last few years for radio work over some of the longest ranges of 3,000, 4,000 or 5,000 miles. It has been adopted for the new G.P.O. station at Leafeld, near Oxford, one of the Imperial Wireless Stations working with the station at Abu Zabal, near Cairo (2,239 miles). (See Figs. 3 and 4.) Arc generators of 1,000 K.W. power have been provided for the Croix d'Hins radio station near Bordeaux, France, erected by the American Army, and the results of their operation are awaited with great interest.

IV. THE HIGH FREQUENCY ALTERNATOR.

10. We must then retrace our steps for a third time over this 21-year period to note the stages of development of a third type of electric oscillation generator, viz., the high frequency alternator.

The earliest workers in this subject who attempted to build alternators with moving coil fields or armatures found difficulties in getting beyond a frequency of 10,000 or so.

By permission of *The Post Office Electrical Engineers' Journal* and Mr. E. H. Shaughnessy.

FIG. 3.—General view of the Buildings and Aerial of the first Imperial Wireless Station at Leafeld, Oxfordshire. Opened August, 1921.

FIG 4 —View of one of the Elwell-Poulsen 250 K.W. generators, as used in the Imperial Wireless Station at Leafeld, Oxfordshire

R. A. Fessenden built in 1907 some small alternators of Mordey type driven by De Laval steam turbines, but E. F. W. Alexander in 1908 directed his attention to the production of a high frequency inductor alternator which has now been made in sizes up to 200 K.W. and for frequencies 20,000 to 100,000 or more. This alternator has been so often described that it is not necessary here to give details. The inductor is a steel disc with its edge cut into teeth, the spaces being filled in with non-magnetic material. These teeth pass between the pole teeth of the field magnet and armature winding, and by varying the magnetic induction through the armature give rise to the induced current. All the stator teeth on one side are of the same polarity, so magnetic leakage is absent. The air gap on each side of the armature is less than 1 mm., hence very special means are required for centering and keeping centered the inductor disc. The chief difficulty in connection with H.F. alternator working is the regulation of the speed. Since a variation of $\frac{1}{4}\%$ in the speed of the 200 K.W. machine would cut down the aerial current to half, it has been necessary to devise arrangements for keeping the speed constant within 0.1%, and this feat has actually been achieved.

11. An important item in connection with this control is the so-called magnetic amplifier, which is a type of choking coil of which the choking power or inductance can be varied over wide limits by more or less magnetizing the iron core by a small direct current. The control of the speed is carried out as follows: —One of the coils of the alternator supplies current to a resonant circuit tuned to a frequency a little below that of the aerial. Part of this current is rectified and made to supply the direct-current control of chokers made as above described, which are inserted in the circuit of the current supply of the 2-phase motor which drives the alternator. If, then, the alternator quickens up its speed, this puts the resonant circuit more out of tune, the saturation current of the chokers is made smaller and their inductance larger, and this checks the speed of the driving motors and brings back the alternator to normal speed.

The same type of variable choker is used

in signalling. The current from the alternator armature passes into the primary coil of an air-core transformer. The secondary circuit is in connection with the aerial and the earth. There is also a tertiary circuit between the two which is closed on a variable choker. If the impedance of the latter is high nearly all the power goes into the aerial, but if the choker core is magnetically saturated by a small direct current, then the tertiary circuit is in effect closed and the power passes into it instead of the aerial. Hence the manipulation of a very small direct current by an automatic key enables a large aerial current to be controlled and signals sent at 100 or more words a minute. Ten alternators of this kind of 200 K.W. size are being installed in the new very large radio station for world-wide working being established by the Radio Corporation of America on Long Island, U.S.A. Alternators of this type have been for some time in use in the United States Naval Radio Station at New Brunswick, New Jersey, U.S.A. Two 200 K.W. alternators of the same kind have been installed in the Marconi Company's large station at Carnarvon, in North Wales, and are working the telegraphic traffic to the United States.

12. A few words must then be said on the Homopolar inductor alternators of MM. Latour and Béthenod. In this case the stator part of the machine is not unlike that of Alexanderson. A circular magnetizing coil is embraced by a saddle-sectioned iron ring in the edges of which are fixed teeth of finely laminated iron. All the teeth on one side are therefore N. poles and on the other S. poles. An armature winding is laid on zig-zag around the teeth. In the centre revolves a drum rotor with laminated iron rings on its periphery which are ploughed out into ridges. These ridges serve to complete the magnetic circuit of the teeth and so vary the flux through the armature coils. In an ordinary inductor alternator there are twice as many teeth on the stator as on the rotor in the circumference. If there are m rotor teeth and the speed is N R.P.M., then the frequency will be $f = mN/60$. The peculiarity of this French alternator is that there are $(2n+1)m$ teeth in the rotor and $2m$ in the stator. Hence the frequency $f = (2n+1)mN/60$. If $n=1$, then there are $3m$ teeth on the rotor and $2m$ on the stator, and we therefore increase the frequency three times without

decreasing the pitch of the stator teeth or raising the speed of the rotor.

Another special feature is that these alternators are enclosed in an air-tight case and run in a vacuum to reduce windage losses due to air churning. In the 220 K.W. alternator the rotor is a steel drum having on it rings of silicon steel 0.03 mm. thick, which are ploughed out in longitudinal grooves. The rotor is 1 metre in diameter and runs at 3,000 R.P.M. This gives 300 periods per revolution, corresponding to a periphery of 314 cms. Hence the pole pitch on the stator is 5 mm., which gives ample space. The rotor is driven by a D.C. motor of 375 K.W. power. The armature is in four sections and the voltage is stepped up by an air core transformer. The signals are made by short circuiting the armature coils.

Alternators of this type of 25 K.W. size are installed in the Lyons Radio Station and a number of 220 K.W. machines are being put in the very large radio station the French Government are completing at St. Assise, near Paris. The Latour-Béthenod alternators above described of the 220 K.W. size are said to have an efficiency of 58% ratio of output on H.F. side to driving power on the rotor. Later machines of 500 K.W. size are said to have 67% efficiency. The frequencies of these larger sizes are 15,000 to 20,000, or for wave lengths of 20,000 to 15,000 metres. A high power radio station equipped with these machines would resemble very closely an electric lighting or power station, with the difference that whereas the latter supplies low frequency currents to underground mains, the former supplies high frequency currents to overhead aerial wires. In many ways the H.F. alternator is an ideal method of generating long electric waves for radio working, and the operations of the new glare alternator radio stations will be watched with great interest. By placing suitable condensers in series with the alternator to reduce their internal reactance, the French engineers have been able to run two or more of these H.F. alternators in parallel on the same aerial. The condenser serves to reduce the reactance and therefore increases the synchronizing power of the machines.

Space does not permit of any reference to the Goldschmidt internal cascade or internal reactive H.F. alternator, which was one of the earliest of the H.F. alternators built for any large power.

In view of the great advances in the simple inductor alternators, it is hardly likely that the more complicated internal cascade alternator will be much used in the future outside perhaps of Germany.

V. THE THERMIONIC OSCILLATION GENERATOR.

13. We must now make a brief reference to the fourth type of electric wave generating appliance which has been developed in the last eight years, in many respects, scientifically speaking, the most interesting of all, viz., the thermionic transmitting valve. So much has been written on it that it is unnecessary to spend a moment in explaining its principles or history.

The great importance of the valve lies in the fact that it is a reversible engine in a thermodynamic sense of the word, and can act both as an amplifier and detector of oscillations, or conversely as an oscillation generator. Its action depends on the copious emission of electrons from an incandescent tungsten filament or from a platinum wire coated with oxides of barium, calcium or strontium. The electron emission may amount to as much as an ampere per square cm. of surface. This electron stream is made to pass from the hot cathode to a cold anode cylinder. In the so-called three electrode form it passes through apertures in a grid or network. The potential of this grid is one factor which determines the resulting electron current, and the appliance is made to act as a generator by a coupling of the grid and plate circuits so that increase in plate current gives a positive potential to the grid and decrease a negative potential. The oscillations then are created in the anode circuit, provided certain conditions are fulfilled, and their energy maintained by a source of direct E.M.F. in the anode circuit. Hence to obtain large power output we have to provide large cathode surface, which implies a large heating current and therefore a large bulb. Owing to the fragility of glass large bulbs made of silica have been to some extent used. We have then to provide a high direct potential to drive the electrons from the hot filament electrode to the anode cylinder, and this is usually done by stepping up a low voltage low frequency alternating current by a static transformer to 5,000 or 10,000 volts or more and then rectifying this current by one or more two-electrode (Fleming) thermionic valves. A number of these oscillating electron tubes can be

worked in parallel and supplied with anode potential from a battery of rectifying valves. Such arrangements are now called a valve panel, and there is no great difficulty in supplying in this manner 150 K.W. to an aerial circuit.

The resulting oscillations are of very pure sine wave form and hence give very sharp tuning.

By suitable proportioning of the circuits it is found that efficiencies as high as 75% or more have been obtained, thus putting the valve efficiency at its best on a level with that of the high frequency alternator and higher than that of the arc generator.

Again, owing to the fact that the grid currents are extremely small, the control of large aerial currents created by valve generators is much facilitated, and there is hardly any practical limit to the speed of signalling with valve transmitters as far as the transmitting appliance is concerned. Furthermore, power expenditure is greatly arrested in the interval between signals, as the anode current is then cut down to zero. In the Report presented to Parliament in June, 1920, by *The Imperial Wireless Telegraph Committee* of 1919-1920 the advantages of valve transmitters were strongly emphasised and their adoption recommended for long-distance Imperial radio stations.

The Marconi Company have recently installed a large panel of generating valves at their Clifden station, which replaces the spark transmitter there formerly used. This panel comprises 12 valves of type MT2, each of 5 to 7 kilowatts capacity. The bulbs are about 7 inches in diameter and 12 inches long. The filaments take 10 amperes at 20 volts for heating, and the anodes are kept at a high potential of 10,000 to 20,000 volts by high tension direct current dynamos run in series. The anode current is about 200 milliamperes at 10,000 volts anode potential.

Using 9 valves, the total anode current is 3.5 amperes for all the valves in parallel with anodes at 18,000 volts. Hence the total feeding power is then 62 kilowatts; including the filament heating power. Such a valve panel conveys to the aerial 47.3 kilowatts, and an aerial current of 260 amperes, assuming a total aerial resistance of 0.7 ohm. This gives a valve efficiency of nearly 75%.

A full description of this valve generator at Clifden was given by Mr. H. J. Round,

in the *Radio Review* for September, 1921. This transmitter gives a very pure sine wave with sharp tuning and strong signals at the receiving stations in Canada and the United States. The success of this plant decided the Marconi Company to instal a still larger valve transmitter of 56 MT2 valves at Carnarvon, which is giving very remarkable and interesting results. Aerial currents up to 350 amperes have been obtained, equivalent to 160 kilowatts put into the aerial.

The engineers of the Company are confident that, with some additions, there should be no difficulty in obtaining aerial currents of 1,000 amperes or more, with a valve transmitter sufficient no doubt for good direct commercial radio-telegraphy to the antipodes.

These facts will show that the future of the valve transmitter is assured. In addition to much less capital outlay than is required for equivalent high frequency alternator or arc plant, there is no necessity for complete duplication to secure reliability, as it is most unlikely that all the valves would fail at once.

VI. RADIATIVE EFFICIENCY OF ANTENNÆ.

14. In connection with all long-distance transmission a question of great importance is that of the radiative efficiency of aerials.

The aerial wire at a transmitting station may be likened to the filament of an incandescent lamp in this respect, that we expend electric power upon it but obtain from it only a fraction of that power in the form of radiation of a desired wave length. The bulk of it is dissipated as heat in the circuits. The form of the aerial is therefore of great importance when we are dealing with large power, because we can thereby regulate the fraction of the power which is dissipated. The radiation resistance (r) of an aerial is generally defined as that numerical quantity by which the square of the aerial current at the base must be multiplied to give the useful radiation in watts. The frictional resistance (R) multiplied by the square of the aerial current gives the power dissipated as heat. Hence the aerial efficiency is $r/(r+R)$. In the earliest days of wireless telegraphy this aerial efficiency was not much above 2 or 3%, but the demands of long-distance working have been the means of bringing about great improvements in this respect.

The efforts of inventors have been directed to the reduction in the ohmic or frictional resistance of the aerial and of the earth plate or balancing capacity, which is the chief cause of inefficiency.

One method by which an improvement has been made is the multiple antenna of Mr. E. F. W. Alexanderson. If we consider a horizontal Marconi directive aerial with terminal down lead wires and tuning coil at one end earthed through a generator, the frictional resistance would be partly in the tuning coil and leads, but also in the earth wires and earth itself.

The radiation resistance of such a flat-top aerial can be approximately calculated from the formula $r=1600h^2/\lambda^2$ where h is the effective height of the horizontal part above the earth and λ is the wave length. Since the frictional losses increase as the square of the aerial current, they rise very rapidly with increase of aerial capacity. In the multiple aerial the horizontal part is earthed through several, say, n , other inductive down leads. The voltage generator is placed in one down lead, and the result is that currents flow in all the other down leads in step with that in the first. We may therefore regard the total aerial current as divided between n down leads each of equal resistance, or as flowing through a joint down lead resistance of $1/n$ th of a single one. Therefore the radiation efficiency is increased from $r/(r+R)$ to $r/(r+R/n)$. Thus, for instance, a certain directive aerial at the New Brunswick Station, U.S.A., had originally a single earth connection. Its radiative resistance was about 0.1 ohm and frictional resistance about 3.7 ohms. Hence its radiative efficiency was about 2.7%. By adding to it 6 suitable inductive down leads each of 0.6 resistance with earth resistance of 2.0 ohms each having a radiation resistance of 0.07 ohm, the aerial efficiency was raised to $14\% = .07/(.07 + \frac{1}{6})$. This was for a wave length of 13,600 metres. By tuning for 8,000 metres the radiative efficiency was raised to 30%. The gigantic radio station now being erected on Long Island, U.S.A., by the Radio Corporation of America, is to have 12 such directive multiple earthed aerials, each 2 kilometres long, arranged like the spokes of a wheel, for transmission and reception in various directions. The oscillations in them will be generated by Alexanderson high frequency alternators of 200 K.W. power. The Polish Government are stated

to have had a contract for a similar large radio station at Warsaw to correspond with the above Long Island Station. Further information on this multiple antenna will be found in an article by Mr. E. F. W. Alexanderson in the *Proceedings of the Institute of Radio Engineers, U.S.A.*, for August, 1920, vol. 8, p. 263, on Trans-Oceanic Radio communication.

The Research Department of Marconi's Wireless Telegraph Company has recently developed another highly ingenious method of reducing the frictional resistance of an aerial and so increasing its radiative efficiency. This method they call an 'Earth Screen Counterpoise.' The following data have been furnished by Mr. H. J. Round, for the Clifden Aerial. This aerial has an effective height of 100 feet, and with the original earth plates, a total resistance of 4.5 ohms. With a wave length of 5,700 metres, it had a radiation resistance of 0.05, and, therefore, a radiation efficiency of 1%. When the earth screen was put in, it reduced the frictional resistance of the aerial to 0.6 ohm; hence, it increased the radiation efficiency to 8%. This aerial is of the directive type, but of very low height. If the height were increased to 100 meters, the result would be a still greater increase in the aerial efficiency to nearly 40%.

Further details will be found in an article by Mr. H. J. Round in the *Radio Review* for September, 1921.

VII. RECEPTION OF WIRELESS SIGNALS.

15. As regards the reception of radio-telegraphic signals, the remarkable discoveries and inventions in the last 17 years in connection with the thermionic valve have made all other types of detector completely antiquated. The properties of the three-electrode valve or triode in respect of amplification and the astonishing sensitivity bestowed on it by re-active and cascade coupling have revolutionised in the last few years the detection of wireless waves. Its present development is due to the inventions and discoveries of numerous investigators of the first rank, and it is difficult for radio-engineers of to-day to put themselves back in thought to the limitations as regards reception existing in pre-valve days. There seems hardly any limit to the variety of ways in which the valve may be used as a wave-detecting device, and as these are now fully described

in numerous text books it is quite unnecessary to occupy time here by any r. petitions. Signals sent from large radio stations can now be detected even at the Antipodes. The real trouble is not to detect the signals but to avoid amplifying at the same time in the same proportion the noises in the telephone due to the natural vagrant waves referred to particularly in a later section.

The direct aural reception by telephone, combined with the use of either high group frequency or high beat frequency in C.W. reception, has the advantage that the skilled operator can take down signals even on a background of disturbing noises due to atmospherics provided it does not exceed a certain degree.

The speed of such reception is, however, limited to 20-30 words a minute more or less.

Automatic recording of various kinds has therefore been invented. We may register photographically on a sensitive film by the use of an Einthoven galvanometer, and the film or strip can be passed through baths, developed, washed, fixed, and dried within a very short time of registration. Or the signal currents can be made to operate the cutting tool of a gramophone or dictophone and record on soft wax cylinders or discs at a high speed, say, 100 words a minute. The disc or cylinder can then be run through a repeating machine slowly, so that a clerk can take down the letter signals as heard and typewrite them instantly.

Furthermore, the old Bain electro-chemical telegraph with chemically prepared paper strip has been revived and the signal currents amplified and rectified by valves can be made to record at astonishing speeds even 400 words or more a minute on the tape. A type of recorder very largely used is one called an Undulator, a sort of syphon recorder in which a pen writes on paper strip square-shouldered notches, short or long, for dots and dashes. It is operated by a rectified amplified valve current.

Finally, by the use of mechanical relays printing telegraphs, such as the Creed Printer or Murray Printer, can be actuated and the letter signals recorded on tape or page form in Roman type, as shown here by Mr. Campbell Swinton not many months ago in this theatre. The oscillation generating properties of the three-electrode valve have made beat or heterodyne reception of continuous waves a simple practical matter, and the receiving operator has

perfect control over the beat frequency to suit himself. In fact, it is the thermionic valve which has made C.W. radiotelegraphy possible at all with certainty and speed. Then again, the immense sensitiveness of valves in series has made it possible to receive over long distance on quite small frame aërials which have directive properties of reception. This assists in cutting out disturbances from other stations and in some degree mitigates the troubles with atmospheric discharges. It also renders quite simple duplex transmission, and it is now the usual thing in long-distance radiotelegraphy to establish the receiving station some miles away from the associated transmitting station and to take up the signals from the distant transmitting station on suitably placed frame aërials, so that sending and receiving go on together. As regards reception, the chief unsolved problem is that of cutting out the atmospheric, which are the chief cause of the necessity for frequent repetitions of messages and words, and therefore of uneconomical delays in transmission.

(To be continued)

OBITUARY.

THE RIGHT HON. FREDERICK HUTH JACKSON.—The Right Hon. Frederick Huth Jackson, who was elected a Life Fellow of the Royal Society of Arts in 1918, died at his residence, Tossingworth, Cross-in-Hand, Sussex, on the 3rd inst.

He was born in 1863, and educated at Harrow and Balliol. On leaving Oxford he began to read for the Bar, but he was offered and accepted a clerkship in the famous firm of merchant bankers, Frederick Huth & Co.; he soon became a partner, and shortly afterwards was elected a director of the Bank of England, at a younger age than any previous recipient of that honour.

Mr. Huth Jackson was Chairman of the Indemnity Mutual Marine, a director of the Eastern Telegraph Company, the Northern Assurance Company, and the London and South-Western Railway; and at one time he was Chairman of the Anglo-Chilean Nitrate and Railway Company. From 1909-11 he was president of the Institute of Bankers. He was also president of the National Alliance of Employers and Employed, and he took the chair at the meeting of the Royal Society of Arts in 1918, when a paper on "The Foundation of Industrial Peace" was read by Mr. A. H. Paterson, Secretary of the Alliance.

He was one of the British delegates at the Hague Conference on bills of exchange, and he took an active part in the discussion that led

to the moratorium. He was also chairman of the Accepting Houses Committee, and worked energetically in the negotiations regarding the pre-war indebtedness of enemy aliens; while later on he acted as treasurer of the Vienna Relief Fund.

He was created a Privy Councillor in 1911.

TRADE IN PERSIAN LAMBSKINS.

According to data supplied by the All-Russian Central Union of Consumers' Societies, Bokhara is the most important city in the Persian lamb-skin trade. The producers bring these lambskins to the bazaars of Bokhara in boxes containing from 50 to 100 skins, where they sell them to the large jobbers, who boil and dry them by special methods, which constitute the first process of preparation.

Prior to the War, the most important markets for skins in this form were Moscow and Nizhni-Novgorod where they were bought by large Russian furriers and foreign firms. The most important of these foreign firms interested were the German firms, which shipped the skins to Leipzig, where special establishments for finishing furs are found.

It appears from a memorandum on this trade, prepared by the Russian Division of the M.S. Bureau of Foreign and Domestic Commerce, that there are three grades of lambskins according to quality.

(1) The best skins come from Bokhara and are distinguished by the thin skin, large dimensions, and small and beautifully arranged curls of splendid lustre.

(2) The skins from Khiva and Afghanistan are inferior, as the hides are thicker and the curls larger.

(3) The skins from Persia, owing to the small dimensions of the skins, their lack of lustre and curls, and their inferior durability make up the poorest grade.

The Persian lambskins from Bokhara are chiefly used for clothing purposes, as jackets and overcoats. These are divided into four grades. The first is distinguished by large curls. The second has small curls in a velour effect, and is mainly used for overcoat collars and capes. The third is called "Kupuc," constituting 5 to 10 per cent. of each bundle when purchased. The fourth grade is named "Karakulch," consisting of hides from still-born sheep and are of small dimensions, having thin skins and small curls. Although the last grade is sold in Russia at prices from 30 to 35 per cent. cheaper than the other grades, the markets of Western Europe and America sell them at prices considerably higher.

Before the War, 2,000,000 to 2,500,000 skins were handled at Bokhara. During the War this number greatly decreased because the borders of the Russian Empire were closed for export. As a result, trade fell off. Prior to 1917, all skins were shipped to the interior of Russia,

but after that year there were no regular shipments.

As a result of this curtailment of shipping there were in June, 1920, estimated accumulations at Bokhara as follows: 1,200,000 skins of 1917; 700,000 skins of 1918; 400,000 skins of 1919; and 200,000 skins of 1920; making a total of 2,500,000 skins.

Beginning with the year 1919 the shipment of furs to Western Europe practically ceased, owing to the poor facilities on the railway between Orenburg and Tashkent. The interruption of the sea route between Krasnovodsk and Astrakhan was also detrimental to this trade.

MEETINGS OF THE SOCIETY.

ORDINARY MEETING.

Wednesday evening, at 8 o'clock.

DECEMBER 14.—SIR WALTER BEAUPRE TOWNLEY, K.C.M.G., Minister to the Netherlands, 1917-19, "Trade with the Netherlands East Indies." THE RIGHT HON. LORD EMMOTT, G.C.M.G., G.B.E., will preside.

Papers to be read after Christmas:—

LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

HOWARD MAURICE EDMUNDS, "Photo Sculpture."

CLOUDESLEY BRERETON, M.A., Divisional Inspector to the London County Council (Modern Languages), "The Necessity of Speech Training, and the Need of a National Conservatoire."

PHILIP SCHIDROWITZ, Ph.D., F.C.S., "Recent Developments in India Rubber Manufacture."

MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work."

JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "Electrical Driving in the Jute Industry."

W. A. APPLETON, C.B.E., Secretary to the General Federation of Trade Unions, "The proper Function of Trade Unions."

EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "Some Solved and Unsolved Problems in Gas Works Chemistry."

ALEXANDER SCOTT, Sc.D., D.Sc., M.A., F.R.S., "The Restoration and Preservation of Objects at the British Museum."

ARTHUR WILCOCK, "Surface Printing by Rollers in the Cotton Industry."

GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

J. H. HUXLEY, "The Control of Sex in Animals."

SIR THOMAS OLIVER, LL.D., D.Sc., M.D., F.R.C.P., "Alcohol in relation to Industrial Hygiene" (Shaw Lecture).

PROFESSOR ERNEST R. MATTHEWS, Assoc.M.Inst.C.E., "Sea Encroachment and its Prevention."

Professor ARTHUR P. LAURIE, M.A., D.Sc., F.R.S.E., "The Permanency of Oil Colours."

J. T. MARTEN, I.C.S., M.A., "The Indian Census" (Indian Section).

ALEXANDER L. HOWARD, "The Timbers of India and Burma." (Indian Section.)

PROFESSOR WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S., "Brown Coals and Lignites: Their Importance to the Empire." (Joint Meeting, Dominions and Indian Sections.)

PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India" (Indian Section).

F. G. ROYAL DAWSON, M.Inst.C.E., Chief Engineer to Indian Railway Board, "The Need for an All-Indian Gauge Policy." (Indian Section.) SIR HENRY PARSALL BURT, K.C.I.E., C.B.E., will preside.

PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow of Magdalene College, Cambridge, *Sir George Birdwood Memorial Lecture*. (Indian Section.)

LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, G.B.E., K.C.M.G., "Queensland." (Dominions and Colonies Section.)

CANTOR LECTURES.

At 8.0 p.m.

MONDAYS.—ARTHUR M. HIND, O.B.E., M.A., Assistant-Keeper, Department of Prints and Drawings, British Museum, and Slade Professor of Fine Art in the University of Oxford, "Processes of Engraving and Etching." Three Lectures.

Syllabus.

LECTURE III—DECEMBER 12.—Etching.—The Process and its Origin—Survey of work by the great original Etchers: Rembrandt, Van Dyck and others—Examination of the special qualities of Etching in relation to different kinds of work—Recent Etching.

C. AINSWORTH MITCHELL, M.A., F.I.C., "Inks." Three Lectures. January 23rd, 30th, and February 6th.

ALAN F. C. POILLARD, F.Inst.P., A.M.I.E.E., late Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington. "The Mechanical Design of Scientific Instruments." Three Lectures. February 20, 27, and March 6.

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, "The Constitutents of Essential Oils." Three Lectures. March 20, 27, April 3.

COBB LECTURES.

At 8.0 p.m.

MONDAYS, F. F. RENWICK, F.I.C., F.C.S., A.C.G.I., "Modern Aspects of Photography." Three Lectures. May 1, 8, 15.

MANN JUVENILE LECTURES.

At 3.0 p.m.

WEDNESDAYS, JANUARY 4 and 11, 1922, WILLIAM REGINALD ORMANDY, D.Sc., "Clay: What it is—Where it comes from—and What can be done with it."

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, DECEMBER 12 University of London, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C., 4 p.m. Mr. F. W. Twort, "Recent Researches on the Biology of Bacteria" (Lecture I.)

Geographical Society, Kensington Gore, S.W., 5 p.m. Mr. F. Dixey, "Photographic Equipment and Methods of Travellers."

Surveyors' Institution, 12, Gt. George Street, S.W., 8 p.m.

Alpine Club, 23, Savile Row, W., 8.30 p.m.

Victoria League, 22, Eccleston Square, S.W., 5 p.m. Mr. C. Henshaw, "The Rocky Mountains of Canada."

East India Association, at Caxton Hall, Westminster, 3.30 p.m. Dr. John Pollen, "The Liquor Question in India."

TUESDAY, DECEMBER 13 Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. A. F. Dabell, "Better Production Methods."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Mr. W. J. Sandeman, "Progress of Gas Lighting in relation to Illuminating Engineering."

Photographic Society, 35, Russell Square, W.C., 7 p.m. (Technical Meeting).

Asiatic Society, 74, Grosvenor Street, W., 4.30 p.m. Mr. Campbell-Thompson, "Modern Babylonia."

Civil Engineers, Institution of, Gt. George Street, S.W., 6 p.m.

University of London, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C., 4 p.m. Mr. F. W. Twort, "Recent Researches on the Biology of Bacteria." (Lecture II.)

British Decorators, Institution of, Painters' Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. S. Hicks, "Art in Modern Education."

Anthropological Institute, 50, Gt. Russell Street, W.C., 8.15 p.m.

Chemical Industry, Society of, and the Chemical Industry Club (Joint Meeting), at the Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. The following cinematograph

films will be shown:—1. The Winning and Working of Sulphur. 2. The Manufacture of Steel (Crucible, Open Hearth, Electric and Bessemer Processes.) 3. The Metallurgy of Zinc.

Faraday Society, at the Chemical Society, Burlington House, W., 7.45 p.m. 1. Annual General Meeting. 2. Prof. A. O. Rankine, "The Structure of Some Gaseous Molecules."

Metals, Institute of (Scottish Section), 39, Elmbank Crescent, Glasgow, 7.30 p.m. Mr. G. E. Fleming, "White Metals."

Electrical Engineers, Institution of (Scottish Centre), 207, Bath Street, Glasgow, 7.30 p.m. Messrs. L. J. Steele and H. Martin, "The Cyc-Arc Process of Automatic Electric Welding."

Textile Institute, 16, St. Mary's Parsonage, Manchester, 4 p.m. Mr. H. Rostrow, "Continued Education."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Sir Charles Lucas, "Balance of Power within the Empire."

WEDNESDAY, DECEMBER 14. Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. Dr. H. F. L. Croult, "Motor Car Gear Boxes."

Microscopical Society, 20, Hanover Square, W., 8 p.m. 1. Mr. E. A. Smith, "The Microscope in Non-Ferrous Metallurgical Research." 2. Drs. J. G. Parker and S. H. Browning, "The Practical Value of the Microscope in Connection with Leather Manufacture."

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 4.15 p.m.

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. H. G. Williams, "The Cost of Living and its Implications."

United Service Institution, Whitehall, S.W., 3 p.m. Colonel R. N. Harvey, "The General Effect of the War in the Principles and Details of Field Engineering."

THURSDAY, DECEMBER 15 Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Captain F. M. Green, "Development of the Fighting Aeroplane."

University of London, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C., 4 p.m. Mr. F. W. Twort, "Recent Researches on the Biology of Bacteria" (Lecture III.)

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. Mr. L. H. A. Carr, "Induction-Type Synchronous Motors."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m.

Concrete Institute, 296, Vauxhall Bridge Road, S.W., 7.30 p.m., Mr. E. F. Sargeant, (a) "The Preparation of Concrete Aggregates." (b) "Moving Forms."

Child-Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Miss Von Wyss, "Vital Elements in Art Teaching."

Camera Club, 17, John Street, Adelphi, W.C., 8.15 p.m. Mr. F. F. Renwick, "The Action of Dyes in Colour Sensitising and Desensitising Dry Plates."

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Architects, Society of, 28, Bedford Square, W.C., 6 p.m.

FRIDAY, DECEMBER 16. Transport, Institute of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Mr. J. Paterson, "The Operation of a Road Distributing Agency."

Metals, Institute of (Local Section), The University, Sheffield, 7.30 p.m. Mr. A. G. Lobley, "Electric Furnaces."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. 1. Mr. R. E. Knight, "Discharge of Grain Cargoes in the Port of London by Pneumatic Elevators." 2. Mr. G. Mitchell, "Conveying and Elevating Machinery."

Photographic Society, 35, Russell Square, W.C., 8 p.m. Address by Mr. L. Richmond.

Announcements intended for insertion in this list must be received at the Society's Office not later than the Monday of the week preceding the meeting.

*For Meetings of the Royal Society of Arts, see page 65.

Journal of the Royal Society of Arts.

No. 3,604.

VOL. LXX.

FRIDAY, DECEMBER 16, 1921

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

SIXTH ORDINARY MEETING.

WEDNESDAY, DECEMBER 7th; HIS
EXCELLENCY THE BELGIAN AMBASSADOR
in the Chair.

The following candidates were proposed
for election as fellows of the Society:—

Hopkins, James Love, LL.B., St. Louis, U.S.A.
Ruddick, James, Quebec, Canada

The following candidates were balloted
for and duly elected Fellows of the Society:—
Ans, C. A. M., Calcutta, India.

Ellis, Alec R., Liverpool
Keller, George J., Bloomsburg, Pa., U.S.A.
Kutar, Kekobad Rustomji, Bombay, India.
Lewis, Samuel Judd, D.Sc., F.I.C., Ph.C.,
London
McCutcheon, Robert Thomson, F.S.A.,
Glasgow.

A paper on "Literature and International
Relations" was read by M. EMILE GAM-
MAERTS.

The paper and discussion will be published
in a subsequent number of the *Journal*.

CANTOR LECTURE.

On Monday evening, December 12th,
MR. ARTHUR M. HIND, O.B.E., M.A., Slade
Professor of Fine Art in the University of
Oxford, delivered the third and final lecture
of his course on "Processes of Engraving and
Etching."

On the motion of the Chairman, a vote of
thanks was accorded to Professor Hind for
his interesting course.

The lectures will be published later on
in the *Journal*.

REPRINT OF CANTOR LECTURES.

The Cantor Lectures on "Recent
Applications of the Spectroscope and the
Spectrophotometer to Science and Industry,"

by SAMUEL JUDD LEWIS, D.Sc., F.I.C.,
have been reprinted from the *Journal*, and
the pamphlet (price 2s.) can be obtained on
application to the Secretary, Royal Society
of Arts, John Street, Adelphi, W.C. 2.

A full list of the lectures which have
been reprinted and are still on sale can also
be obtained on application.

MANN JUVENILE LECTURES.

Under the Mann Trust a short course
of lectures adapted to a juvenile audience
will be delivered on Wednesday after-
noons, 4th and 11th January, 1922,
at 3 p.m., by Mr. William Reginald
Ormandy, D.Sc., F.I.C., on "Clay: What
it is—Where it comes from— and What
can be done with it." The lectures will
be illustrated with experiments.

Special tickets are required for these
lectures. A sufficient number to fill the
room will be issued to Fellows in the order
in which applications are received, and the
issue will then be discontinued. Subject
to these conditions, each Fellow is entitled
to a ticket admitting two children and one
adult. Fellows who desire tickets are
requested to apply to the Secretary at
once.

LIST OF FELLOWS.

The new edition of the List of Fellows of
the Society is now ready, and copies can be
obtained on application to the Secretary.

CASES FOR JOURNALS.

Cases for keeping the current numbers
of the *Journal* are now obtainable. They
are in red buckram, and will hold the
issues for a complete year. They may be
obtained post free, for 7s. 6d. each, on
application to the Secretary.

BINDING COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers can be supplied, post free, for 2s. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

WEDNESDAY, NOVEMBER 23RD, 1921.

MR. ALAN A. CAMPBELL SWINTON, F.R.S.,
Chairman of the Council, in the Chair.

THE COMING OF AGE OF LONG DISTANCE RADIOTELEGRAPHY AND SOME OF ITS SCIENTIFIC PROBLEMS—PART II.

By J. A. FLEMING, M.A., D.Sc., F.R.S.
Albert Medalist of the Royal Society of Arts

FIFTH TRUEMAN WOOD LECTURE.

(Continued from page 74)

VIII. PROPAGATION OF ELECTROMAGNETIC WAVES ROUND THE EARTH.

16. The achievement of transatlantic radiotelegraphy in 1901 and 1902 was of interest to physicists chiefly by reason of the fact that they did not see clearly why it should have been possible at all. The mystery of it was increased when at subsequent dates radio signals were transmitted a quarter of the way round the world, and finally, with high power stations and thermionic valves detected even at the Antipodes.

The wave length of the waves used in the earliest work at Poldhu was about 3,000 feet, although not accurately measured in those days.

The earth, roughly speaking, is a sphere 42 million feet in diameter. Hence the ratio of wave length then used to earth diameter was about 1 : 14,000.

In the case of light there is a small bending or diffraction of the wave round an opaque obstacle. In other words, there is some small amount of illumination within the boundary of the geometrical shadow. The average wave length of light waves is about 1/2,000th of a millimetre, and a sphere having a diameter of 7 mm. would be 14,000 of such wave lengths. Now if an exceedingly small source of light was placed

on the pole of a sphere 7 mm. in diameter in a dark region, it is certain that there would be no illumination at the equator of the sphere. In other words, there would not be any sensible diffraction at an angular distance of 90°. Modern long-distance radiotelegraphy conducted with waves of wave length approximating to 10 miles or so can communicate even with the Antipodes.

It therefore became of great interest to consider the question of the diffraction of long electromagnetic waves round a conducting or semi-conducting sphere at the pole of which a Hertzian oscillator was placed with the axis radial. The object of the investigation is to find a mathematical expression for the magnetic and electric forces at any point on the surface of the sphere removed from the oscillator by an angular distance θ . The problem is by no means easy and has engaged the attention of many most eminent mathematicians and caused much discussion. It was first attacked by Professor H. M. Macdonald⁽⁵⁾ in 1903, but the amount of diffraction which he obtained was relatively large and his results were criticised by the late Lord Rayleigh⁽⁶⁾ and by M. Poincaré⁽⁷⁾. Macdonald⁽⁸⁾ then revised his calculations and found that at large angular distances the diffraction was certainly small. In a subsequent paper Macdonald⁽⁹⁾ attacked the problem again and gave numerical results for wave lengths of 0.2 mile (=320 metres) and 0.25 mile (=400 metres) in the form of a table showing the ratio of the amplitude of the oscillations at the receiver to the amplitude at the same point if the earth were supposed removed, for various angular distances. His calculations were, however, made for wave lengths far shorter than now employed, and since the diffraction is greatly affected by wave length these early numerical results are no longer of interest. The subject was then discussed by Prof. J. W. Nicholson⁽¹⁰⁾ in a series of able papers in the *Philosophical Magazine*, and the mathematical treatment led to discussions between himself and Prof. Macdonald.

(5) H. M. Macdonald. *Proc. Roy. Soc.; Lond.* Vol. 71, p. 251. 1903.

(6) Lord Rayleigh. *Proc. Roy. Soc.; Lond.* Vol. 72, p. 40 (1904).

(7) Poincaré, H. *Proc. Roy. Soc.; Lond.* Vol. 72, p. 42 (1904).

(8) H. M. Macdonald. *Proc. Roy. Soc.; Lond.* Vol. 72, p. 59 (1904).

(9) H. M. Macdonald. *Phil. Trans. Roy. Soc.; Lond.* Series A Vol. 210, p. 113 (1910).

(10) J. W. Nicholson. *Phil. Mag.* (Ser. 6). Vol. 19, pp. 516, 757 (1910). Vol. 20, p. 157 (1910), and Vol. 21, pp. 62, 281 (1911).

The numerical results deduced from the formulæ as given by Nicholson and Macdonald (11) respectively do not, however, agree. Dr. Van der Pol (12) has pointed out a small mathematical slip in Nicholson's analysis which, when rectified, brings his formula into better agreement with that of Macdonald for short distances. The problem of the transmission of electromagnetic waves over the earth was next critically discussed by Prof. A. E. H. Love (13) in 1914, and his results compared with Macdonald's conclusions. In the case when the earth is assumed to be a perfect conductor Love found complete agreement between his formulæ and those of Macdonald for the ratio of the magnetic and electric forces at two stated angular distances from the transmitter when these distances reckoned as angles along a meridian are not smaller than 6° or 7° and not greater than about 20° .

17. The mathematical treatment of the problem of the diffraction of electric waves round a conducting sphere which are radiated from a transmitter at its pole consists in expressing the magnetic and electric forces at any angular distance θ in the form of a series of harmonic terms. It is in the summation of this series to obtain the integral effect at the receiver that the chief difficulties and differences of opinion occur, and most analysts employed only an approximation.

In 1918 Prof. G. N. Watson (14) effected a new and complete summation which enables the value of the forces to be calculated for any point on an imperfectly conducting sphere.

The results obtained by Watson are in close agreement with those of Nicholson when the formula of the last-named mathematician is corrected for the slip noted by Dr. Van der Pol (15). The final conclusions can be presented as follows:—Let there be two receiving stations on a meridian at angular distances θ_1 and θ_2 (reckoned in radians) measured from the transmitter station. Let H_1 and H_2 be the amplitudes of the magnetic force at these two stations due to continuous electromagnetic waves sent out from the transmitter.

$$\frac{H_1}{H_2} = \frac{\cos \frac{1}{2} \theta_1 \sqrt{\sin \frac{1}{2} \theta_2}}{\cos \frac{1}{2} \theta_2 \sqrt{\sin \frac{1}{2} \theta_1}} e^{-47.9 \lambda^{-1} (\sin \frac{1}{2} \theta_2 - \sin \frac{1}{2} \theta_1)}$$

where λ is the wave length.

According to Nicholson, Van der Pol and Watson

$$\frac{H_1}{H_2} = \frac{\sqrt{\sin \theta_2}}{\sqrt{\sin \theta_1}} e^{-23.9 \lambda^{-1} (\theta_2 - \theta_1)}$$

The difference between the above formula is not large for angles, such that $\cos \frac{1}{2} \theta$ is nearly unity, and under these conditions, which hold when θ_2 or θ_1 do not exceed, say, 20° , or a meridian distance of, say, 2,000 kilometres, we may employ either formula, but for longer distances the second formula is more exact.

As it is more convenient to work with antenna currents than magnetic forces, Dr. Van der Pol has converted the above second formula into another, as follows:—

$$\frac{I_2}{I_1} = 0.5368 \frac{1}{\sqrt{\sin \theta}} \frac{\alpha_1 h_1 \alpha_2 h_2}{\lambda^{7/6} R_2} e^{-23.9 \theta \lambda^{-1}}$$

Here I_1 and I_2 are the ampere currents at the base of the sending and receiving aeriols respectively, θ is the angular meridian distance of them in radians, λ is the wave length in kilometres, h_1 and h_2 are the heights in kilometres of the aeriols, α_1 and α_2 are form factors giving the ratio of the mean aerial currents to the currents at the base, and R_2 is the equivalent resistance (including radiation resistance) of the receiving system reckoned in ohms. The above formula is valid for a perfectly conducting earth surrounded by a perfectly insulating atmosphere.

It is more convenient to measure the distance (d) of the stations in kilometres measured along the earth's surface, and in that case the exponential factor in the last formula becomes

$$e^{-0.00376 d \lambda^{-1}}$$

18. The result, then, of 18 years' work on this problem by mathematicians of the highest rank has been to give us a formula for the current in a receiving aerial of given resistance determined in terms of wave length, aerial heights and distance which represents the result of pure diffraction acting round a spherical earth of perfect conductivity. On the other hand, when we come to compare the results of this diffraction formula with actual observations in practice we find an enormous discrepancy.

(11) H. M. Macdonald. *Proc. Roy. Soc.; Lond.* Vol. 90, p. 50 (1914).

(12) Dr. Balth Van der Pol *Phil. Mag.* Vol. 38, p. 365 (1919).

(13) A. E. H. Love. *Phil. Trans. Roy. Soc.; Lond.* Series A. Vol. 215, p. 105 (1915).

(14) G. N. Watson. *Proc. Roy. Soc.; Lond.* Series A. Vol. 95, p. 83 (1918).

(15) B. Van der Pol. *Phil. Mag.* Vol. 38, p. 377. September, 1919.

The actual received currents in the case of long-distance stations for given sending aerial currents are hundreds of thousands, or even millions, of times greater than the received current predicted by the theoretical formula.

Thus, to take a case quoted by Dr. Van der Pol from observations made at Darien Radio Station on the Panama Canal on radio signals sent from Nauen, near Berlin. Dr. L. W. Austin gives the following figures: $I_1 = 150$ amps, $\lambda = 9.4$ kilometres, $a_1 h_1 = 120$ metres, $a_2 h_2 = 146$ metres, $R_2 = 29$ ohms, and $d = 9,400$ kilometres.

Now the actual received current was $I_2 = 1.3$ microamperes, but the value predetermined by the formula is only 0.6 of one millionth of a microampere. In other words, the actual received current in this case is 2 million times greater than the predicted current. Even if there is a large percentage error in the measurement of the received current, this will not make matters much better. Nor will the finite conductivity of the earth's surface account for it. About three-quarters of the earth's surface is sea water, and the absolute conductivity of this for high frequency currents is about 10^{-11} , an electromagnetic unit, equivalent to a specific resistivity of 100 ohms per centimetre cube. Nevertheless, investigations have shown that even this finite conductivity cannot increase the received aerial currents to any very great extent.

The upshot of the whole matter then is this:—Long-distance radiotelegraphy, say, round one-quarter of the circumference of the earth, would certainly be quite impossible but for some cause, other than diffraction, operating to compel the waves to follow round the earth's curvature and not quickly glide off it.

19. Oliver Heaviside in 1900 suggested that an upper conductive layer on the atmosphere might act as a guide to the waves, radiotelegraphy being, in fact, conducted in a thin spherical shell of non-conductive air bounded by a conductive earth and a conductive upper air.

He did not furnish any valid reasons to explain why this upper air conducts and how its conductivity is preserved, and although the suggestion has been very generally accepted by radio engineers, it has been taken without sufficient criticism of its difficulties and details. There has been in the intervening 21 years an immense

accumulation of facts, all showing, however, that long-distance radiotelegraphy is conditioned by the physical constitution of our atmosphere and is very far removed indeed from being simple electromagnetic wave propagation in empty space. An important epoch in this connection is the date 1902, when Senatore Marconi (16) discovered during one of his early voyages across the Atlantic in the *s.s. Philadelphia* in February, 1902, that radio signals from Poldhu could be received at night about thrice the distance they could be read in daytime, being detectable only up to 700 miles by day, but readable up to 2,099 miles by night.

It was at once surmised that the difference was due to ionisation of the air by sunlight, which, by liberating electrons from atoms, gives to the air conductivity. It was some years before this vague suggestion was converted by Dr. W. H. Eccles (17) into a more definite scientific theory, many speculations in the meantime being found wanting in adequate basis, such as that which regarded the sunlit air as having an absorption for the energy of electro-magnetic waves similar to that of foggy or misty air for visible light.

20. Before entering into further discussions of the facts, it will be convenient to mention a few of the generally accepted views as to the constitution of the terrestrial atmosphere and its ionisation by light.

By the use of hydrogen-filled sounding balloons carrying self-recording meteorographs, it has been possible to explore the atmosphere up to a height of about 20 miles. One of the results is to show that our atmosphere may roughly be divided into two regions. In the lower layer, called the *troposphere*, the atmospheric gases are kept well mixed up by winds and convection. This layer extends to a height of 6 or 7 miles or so, and in it the temperature falls regularly with increasing height at the rate of about 6°C . per kilometre of ascent until a temperature of about -55°C . is reached. Above this is a zone called the *stratosphere*, of unknown thickness, in which the temperature remains constant. Above a height of about 7 miles water vapour is absent, and at higher levels convection ceases to operate and the atmospheric gases arrange themselves in order of density.

(16) G. Marconi. *Proc. Roy. Soc.; Lond.* Vol. 70, p. 344 (1902).

(17) W. H. Eccles. *Proc. Roy. Soc.; Lond.* Series A. Vol. 87, p. 79 (1912).

The outer and highest levels above a height of 60 miles (=100 kilometres) are chiefly composed of Helium and Hydrogen with possibly some small admixture of the rarer atmospheric gases Neon and Krypton.

* The volume composition of the atmosphere at the earth's surface is as follows:—

Nitrogen	..	78.05%.
Oxygen	..	21.00%.
Argon	..	.93%.
Carbon dioxide	..	.03%.
Hydrogen	..	1 to 10 vols. in a million of air.
Neon	..	10
Helium	..	1 to 2
Krypton	..	1 vol.
Xenon	..	.05

Oxygen is almost entirely absent at a height of 100 kilometres, but nitrogen is still present in a rarified form. The presence of hydrogen and helium at these high levels has been indicated by an observation of Pickering on the spectrum of a meteoric stone entering the earth's atmosphere, which showed the hydrogen and helium lines.

21. Next, as regards the action of light on these gases. Light waves of high refrangibility impinging on nearly all substances, especially those containing electropositive atoms, liberate from them electrons. The atom is now considered to be a collocation of negative electrons arranged in concentric shells, possibly in orbital motion, round a central positively charged nucleus in which the gravitative mass of the atom chiefly resides.

Light of short wave length causes one or more of these negative electrons to be detached and projected with a high velocity. The more electronegative an atom is the higher must be the frequency of the light to affect it. The electrons so detached are called photoelectrons and the action photoelectric.

In the case of sodium or potassium, which are highly electropositive metals, photoelectrons are emitted under the action of visible light, about the middle of the spectrum, but for less electropositive metals, e.g., zinc and magnesium, the action only takes place with ultra violet light. Hence it follows that a plate of zinc illuminated by light from an electric arc or by the spark between aluminium balls loses a negative charge readily, and if insulated, becomes positively electrified owing to the loss of negative photoelectrons. The velocity with which these photoelectrons are projected is considerable, and may be

500 to 1,000 kilometres per second. A certain energy (W) has to be expended to detach an electron from an atom, and if its mass is m and maximum emission velocity v , its maximum kinetic energy will be $\frac{1}{2}mv^2$ and the total energy imparted to it must be $W + \frac{1}{2}mv^2$. It has been found that this total energy is proportional to the light frequency and to a constant, called Planck's Constant ($=6.55 \times 10^{-27}$ C.G.S. units). We can represent this work as the product of a certain voltage (V) called the ionising potential and the electron charge e ($e=4.8 \times 10^{-10}$ electrostatic units or $=16 \times 10^{-21}$ electromagnetic units). Hence, if we neglect the energy W , which is relatively small, we have the equation.

$$\frac{V \times 10^8 \times 16}{10^{21}} = \frac{6.55 \times 3 \times 10^{10} \times 10^8}{10^{27} \times \lambda}$$

where V is the ionising potential in volts and λ the light wave length in Angström units (1 A.U. = 10^{-8} cm.). This gives $V\lambda=12,000$.

For most metals the ionising potential is about 2 to 4 volts, hence the maximum wave length of ionising light is just beyond the violet end of the visible spectrum. But for atmospheric gases, when pure and free from dust or moisture, the ionising potential is much higher, being approximately as follows:—

Nitrogen	..	7.5 volts.
Oxygen	..	9 ..
Hydrogen	..	11 ..
Argon	..	12 ..
Neon	..	16 ..
Helium	..	20.5 ..

It follows from this that the atmospheric gases cannot be ionised by light of longer wave length than 1,350 A.U. Rays of this short wave length are not transmitted by quartz but only by certain samples of fluorite, and are absorbed by a very small thickness of air. No sunlight of shorter wave length than about 2,950 A.U. reaches the earth's surface, as shown long ago by Huggins and Cornu.

Hence the conclusion is forced on us that pure dust-free atmospheric gases cannot be ionised at the lower levels of the atmosphere by the direct action of sunlight, but at the higher levels above 60 to 100 kilometres doubtless there is direct ionisation.

Nevertheless, ionisation does take place in the lower atmospheric levels, as shown by the small finite electric conductivity possessed by the air, which proves that

there are negative ions, either free electrons, or electrons attached to neutral atoms, and also positive ions present in the air, even over wide oceans. Thus, Boltzmann found in tests made in mid-Atlantic 1,150 positive and 800 negative ions in the air per c.c. A. S. Eve found 600 to 1,400 positive and 500 to 1,000 negative per c.c., the positive ions being slightly in excess.

This ionisation may be produced either by photoelectric action on dust or ice particles in the air, or by radio active matter in the soil, or photoelectric action upon complex gaseous molecules in the air, or generated by the light and called condensation nuclei.

Such agencies, however, cannot account for the far larger and permanent ionisation necessary to give the required electric conductivity in the higher atmosphere if it is to act as a guide to long electromagnetic waves. The conductivity of a gas is related to number of ions and ionic freedom of movement as follows. If there are n_1 positive ions and n_2 negative per c.c., and if the $+$ ions acquire a velocity v_1 cms. per second under an electric force of one volt per centimetre, and the $-$ ions a velocity of v_2 , then the total current I through the gas under a voltage V is $I = (n_1 v_1 + n_2 v_2) e V$ where V is the impressed voltage. If we take v_1 nearly equal to v_2 and n_1 nearly equal to n_2 , this becomes $I = n v e V$ where n is the total number of ions and v their average added velocities under unit electric force respectively. Rutherford found that for air at normal temperature and pressure the value of v is about 2×1.4 cms./sec., or, say, 3 cms./sec., and for hydrogen $v = 2 \times 3.9 = 7.8$ cms./sec. Since 1 volt = 10^8 electromagnetic units, this gives $v = 3/10^8$ for air and $e = 16/10^{21}$ using electromagnetic units. The ratio $1/V$ is the absolute conductivity, and hence $1/nev$ gives us the specific resistance in electromagnetic units. Supposing, then, that $n = 2,000$, then we should have

$$2,000 \times \frac{3}{10^8} \cdot \frac{16}{10^{21}} = \frac{96}{10^{26}} = 10^{24} \text{ conductivity in E.M.U.} = 10^{15} \text{ ohms resistivity.}$$

This would make the specific resistance of the air at normal temperature and pressure about 1,000 million megohms per c.c.

Even if there 10,000 ions per c.c. present, this would only make the specific resistance 50 million megohms per c.c. and hence practically a perfect insulator.

22. A consideration of the terrestrial radiotelegraph problem shows that if there is any conductive layer in the upper atmosphere which can act as a guide to long electromagnetic waves round the earth, it must possess the following properties:—

(1.) It must be permanently ionised, which means that its ionisation must not vanish in the night-time since, as far as we know, its guiding powers are not suspended on the shadow side of the earth. This seems to imply that the ionisation must be predominantly of one sign or that the $+$ and $-$ ions are so far separated that they do not readily re-combine.

True gaseous photo-ionisation always produces ions of both signs in equal number mixed up together and the conductivity quickly disappears when the ionising agency is withdrawn.

(2.) The resulting electric conductivity must be sufficiently high, say, as good as that of ordinary fresh water to act as a true wave guide. This implies that the ions must be very numerous per c.c. and very mobile or have high ionic velocities under unit electric force.

The specific resistance of fresh water is from 1 to 5 megohms per centimetre cube more or less. That of sea water about 20 to 100 ohms per c.c.

Dilute sulphuric acid of maximum conductivity (battery acid) has a specific resistance of 6 ohms per c.c. The velocity of gaseous ions under unit electric force varies inversely as the gaseous pressure, at least approximately. If p_0 is the density of the air at the earth's surface and p is the density at a height of h kilometres, then it is easy to show that

$$2.3026 \log_{10} \frac{p_0}{p} = \frac{gh}{RT10^5}$$

where g is the acceleration of gravity, T absolute temperature and R is the gas constant. Since $R = (83 \times 10^6)/M$ where M is molecular weight we have approximately

$$\log_{10} \frac{p_0}{p} = \frac{M}{2} \frac{h}{T}$$

Suppose, for simplicity, we take the atmosphere to have an average molecular weight of 20, and if we assume the average temperature to be 200° absolute, we find that at a height of 100 kilometres the density of the air would be about ten millionths of its density at the surface. The ionic

velocity under unit electric force might therefore be about

$$\frac{28}{10^9} \times 10^5 = \cdot 0028 \text{ cm/sec.}$$

If then there are 10^6 or 1 million ions per c.c. the specific resistance would be

$$\rho = \frac{10^{21}}{16} \frac{10^4}{28} \frac{1}{10^6} \frac{1}{10^9} \text{ ohms} \\ = 20 \text{ megohms, nearly.}$$

If there are only 10^5 ions per c.c. the resistivity would be about 2 megohms per c.c.

Bearing in mind that the upper regions of the earth's atmosphere above 100 kilometres level probably chiefly consist of hydrogen, and that the velocity of ions in hydrogen under unit electric force is, according to measurements, from 2 to 3 times that in oxygen or nitrogen at the same pressure, it is easily seen that in the upper hydrogen levels of the atmosphere a very moderate amount of ionisation, say, 10^7 ions per c.c., might give a conductivity of the order of that of fresh water, or about 700,000 ohms per centimetre cube.

(3.) Another quality this conducting layer must possess if it is to act as a true reflector of long waves is a somewhat sharply defined lower surface. When a ray passes from one medium to another true reflection will only take place if the change in conductivity or dielectric constant is very marked within the limits of a wave length or so. If the transition is gradual or irregular the regular reflection will not be found. If the periodic time of the wave is T , and if the conductivity is s , then the ratio of the intensity of the reflected ray to that of the incident is very nearly

$$1 - \frac{2}{sT}$$

This becomes unity if either conductivity or wave length are very large. Hence it is not sufficient to have an upper ionised layer in the atmosphere if it is to act as a guide to the waves. The conducting layer must have a somewhat sharply defined under surface.

23. It has already been remarked that observations on signal strength over long distances show an enormous difference between the actual measured values and those predicted by a simple diffraction formula.

A large number of observations have been taken at various times of signal strength or receiving aerial currents for

distances up to 3,000 miles or so, and the results recorded in curves (18).

Attempts have then been made to find an empirical formula for the received current in terms of the other quantities involved.

At first these efforts started with the erroneous assumption that the attenuation might be regarded as due to an "absorption" caused by the atmosphere, and therefore mathematically represented by an exponential factor appended to the simple Hertzian expression for the magnetic or electric force at a known distance on the equatorial plane of a small oscillator.

A factor was subsequently added to correct for curvature of the earth and the empirical formula generally known as the Austin-Cohen formula is now given as follows:—

$$\frac{I_r}{I_s} = \frac{377 h_1 h_2}{\lambda d R} \sqrt{\left(\frac{\theta}{\sin \theta} \right)} e^{-0.0015 d / \sqrt{\lambda}}$$

where h_1, h_2 are the effective heights of the transmitting and receiving aerials, d their distance and λ the wave length, all measured in kilometres, θ is the angular meridian distance of the stations and R the total resistance of the receiving circuit in ohms. The numbers 377 and 0.0015 ($=\alpha$) are empirical constants.

If in the exponent we put θ instead of d , then the exponential factor becomes

$$e^{-9.6 \theta / \sqrt{\lambda}}.$$

This formula is stated to be valid up to a distance of about 2,000 miles, but to bring it into accord with observations several modifications of it have been suggested. However well it may fit in with observations taken over a limited range, it is nevertheless a purely empirical formula and cannot safely be extrapolated. If it is compared with the theoretical diffraction formula already given it will be seen that the chief difference is in the exponential factor which in the latter is $e^{-23.9 \theta / \lambda^{1/3}}$.

As this last expression was derived for the case of a spherical earth in free space, it appeared desirable to re-consider the diffraction problem, but assuming an enveloping spherical shell of semi-conducting material

(18) See L. W. Austin. Some Quantitative Experiments in long distance radiotelegraphy. Bulletin of The Bureau of Standards, Washington. Vol. 7 No. 3, 1911. Also T. L. Hogan, Jr. The Electrician. August, 8th, 1913. Vol. 71, p. 720.

surrounding the earth at a height of about 100 kms.

Professor G. N. Watson⁽¹⁹⁾ accordingly took up this question and has given recently a solution of it. He finds that if in place of a perfectly conducting spherical earth in free space we assume an earth having a conductivity about the same as sea water, enclosed in a spherical sheath or shell of material having a conductivity of about 1.44×10^{-15} E.M.U., equal to a specific resistance of 700,000 ohms per c.c. or not far from that of ordinary fresh water, the interspace being about 100 kilometres, then the diffraction formula for the receiving aerial current would have to be modified and the exponential factor would become

$$-9.6 \theta / \sqrt{\lambda} \text{ in place of } -23.9 \theta \lambda^{-1}$$

and there would be agreement with the Austin-Cohen formula. Watson therefore considers that if we are able to assume an upper conducting layer in the atmosphere at a height of about 100 kms. having a fairly sharp under-surface and a specific resistance of about 700,000 ohms or, say, 0.75 megohm per c.c., then guided wave propagation through the included spherical shell of insulating air would account for the observed attenuation in actual terrestrial long-distance radiotelegraphy.

24. We have then to consider what are the probabilities and possibilities for the existence at a height of 100 kilometres or so of such a conducting layer and how it may be supposed to become ionised.

It may be remarked in passing that mere rarefaction in a gas does not of itself bestow electric conductivity. It is sometimes said that gases at a pressure of a millimetre, or perhaps less, are good conductors, as instanced by the ease with which an electrodeless discharge can be created in them by a high frequency alternating magnetic field.

Gaseous conductivity is, however, always and only due to the presence of ions, and in the above case these are created by the strong electromotive forces brought into play. In gases contained in glass vessels there are always some few free ions or electrons present for some reason. If a high frequency magnetic field is made to act on the gas these ions are driven with great force against the gas molecules and ionise them, thus producing very quickly

a copious supply of ions and giving the gas high conductivity. We cannot, however, say that a rarefied gas is a good conductor *per se* for very feeble impressed electromotive forces as we can say that a metal is a good conductor. Hence mere rarefaction due to height will not bestow the required electric conductivity on the atmosphere. Neither can the required ionisation be produced by solar light, because then it would vanish in the night-time by re-combination of the ions.

25. The suggestion I wish to make as to the cause of this ionisation is based upon a modification of hypotheses already advanced by S. Arrhenius⁽²⁰⁾, K. Birkeland, and by W. J. Humphreys⁽²¹⁾, concerning the projection of dust by light pressure from the sun.

We know that the sun's photosphere is in a continual state of disturbance due no doubt to violent explosions in regions beneath this light-giving locality. Above this photosphere lies the so-called reversing layer composed of metallic vapours which produce the Fraunhofer lines in the spectrum. These eruptions carry up not only metallic vapours, but also vast masses of the superlying chromosphere composed chiefly of hydrogen and helium gases in the form of solar prominences or red flames which are often seen rising to a height of several hundred thousand kilometres in a few minutes, thus indicating velocities of several hundred kilometres per second. When these solar metallic vapours are thus carried up into colder regions they must be condensed into a metallic mist or rain composed of particles of various sizes. We know also from experiment as well as theory that light exercises a pressure on solid objects and that this pressure per square cm. for totally absorbing or black bodies is numerically equal to the light energy in the cm. cube. Measurements made of the so-called solar constant at the earth's surface when corrected for atmospheric absorption give a value of 2.5 gram calories per sq. cm. per minute. Hence the energy of light per c.c. is nearly $6/10^5$ ergs and the light pressure therefore $6/10^5$ dynes per sq. cm. on a black surface. But at the sun's surface this pressure is 46,000 times greater, or 2.75 dynes per sq. cm. As this pressure

varies as the square of the linear dimensions of the particle whilst gravitation varies as the cube, it is clear that as the dimensions of a particle decrease a limit will be reached at which the light pressure will overbalance the gravitation attraction.

It is easy to prove from known data that at or near the sun's surfaces black particles of the density of water would be just repelled if they had diameters of 15,000 Angström units $= 150/10^6$ centimetre.

If their density is 5.5, then the critical diameter will be 2,700 A.U. If, however, the particles have diameters of only 1,600 A.U. and unit density the light pressure will be 19 times greater than the gravitation attraction. For sizes still smaller the light pressure would decrease again, and for diameters less than 500 A.U. gravity would once more preponderate. (See Fig. 5.)

FIG. 5.—Curve showing the variation of the ratio of light pressure to gravitation for particles of unit density and various diameters

If, then, the solar eruptions drive up into colder regions vapours which are condensed to liquid or solid particles, a sorting action will at once come into play. Particles above a certain diameter will be drawn back into the sun. Particles below a certain diameter will be repelled away with great force by light pressure, and particles of a certain critical diameter will remain suspended in space. The solar corona may perhaps be in part composed of solar dust of this critical diameter, as Arrhenius has suggested. Now, as regards that dust which is repelled by the sun, it is easy to calculate the time particles of certain sizes will take to travel to the

earth's orbit and the velocities they will then possess. Taking the particles to have unit density and three sizes, viz., 1,600 A.U., 5,000 A.U., and 10,000 A.U., and to be projected from the sun with velocities of 200 kilometres per second, I find that the times required to travel to the earth's orbit will be respectively 22 hours, 42 hours, and 76 hours.

The velocities with which they will arrive will be 1,700 kilometres per sec., 780 kms. per sec., and 350 kms. per sec. respectively.

26. These minute particles, composed, it may be, of carbon from the photosphere or metallic dust from the reversing layer or volcanic ash or other solar materials will in general carry electric charges. The high temperature will cause emission of electrons from the metallic particles, as also will the fierce ultra violet radiation to which they are exposed. The metallic vapours will also be in a state of ionisation, and the free electrons emitted will condense round them gases or vapours from the chromosphere as they pass through it. Hence the particles which are repelled by light may be either positively or negatively electrified or neutral. Owing to the greater tendency of negative electrons to condense vapours and attach themselves to groups of molecules, the negatively charged particles may be less dense and smaller than those positively charged. It should be noted, however, that isolated molecules or electrons are far too small in diameter to be repelled by light. It is only groups of molecules of at least 500 A.U. in diameter which can be repelled. Hence these dust particles will travel outwards from the sun with very different velocities. Some will come with great velocity and others with small speed.

In short, we may say that the sun, like a good housemaid, dislikes dust, especially dust of a certain degree of fineness, and pushes it away from it with great force. The moment that this electrified dust enters the earth's magnetic field with high velocity, forces will be brought to bear on it tending to separate the negatively and the positively charged particles. If H is the magnetic force of the earth and v the particle's velocity, and e its charge, then the separating force is Hev where H is that component of magnetic force at right angles to the direction of v and the separating force is also at right angles to the plane of H and v .

27. Another cause operating to effect a separation of the positively and negatively charged dust is found in the viscosity of the atmosphere. Roughly speaking, the viscosity of a gas is that quality of it in virtue of which fine particles experience a resistance in moving through it. Maxwell⁽²²⁾ showed long ago that the viscosity of a gas is independent of the pressure over wide limits. Crookes continued these researches and demonstrated that between atmospheric pressure and a pressure of about one ten-thousandth of an atmosphere the viscosity remains constant, but that when the pressure falls below this last figure the viscosity very rapidly decreases to zero. Again, both Maxwell and Crookes found that the viscosity of hydrogen is about half that of oxygen or nitrogen. (See Fig. 6.)

FIG. 6—Variation of Viscosity with pressure for various gases (Crookes).

The viscosity of air at 760 mm. is 0.00018 C.G.S. units.

Sir George Stokes proved that if a small sphere of diameter d and density σ is falling through a gas of density ρ and viscosity μ under the action of gravity it will attain a final velocity v such that

$$v = \frac{1}{18} \frac{d^2 g}{\mu} (\sigma - \rho)$$

where g is the acceleration of gravity. This explains the extremely slow rate of fall of water particles constituting clouds, and also the very slow settlement of fine dust particles through air.

The positively charged solar dust particles are probably larger than the negatively charged particles, as the latter consist of electrons having condensed round them molecules of gases, probably hydrogen and helium, gathered from the solar chromosphere. Accordingly the negative ions will be brought to rest before the positively charged particles and gas viscosity will assist the separation. Stokes showed that a small particle of diameter d moving with a velocity v through a gas of viscosity μ is losing kinetic energy at a rate $3\pi d\mu v^2$. Hence, if m is the mass of the particle,

$$m \frac{dv}{dt} = -3\pi d\mu v^2$$

The solution of this equation is

$$v = V_0 e^{-3\pi d\mu t/m}$$

$$v = V_0 e^{-\frac{3\pi d\mu t}{m}}$$

where V_0 is the initial velocity. If we consider that the particle is practically at rest when $v = 1$ cm. per second, then we have for the time t in which its velocity is reduced from V_0 to 1 cm. per second the equation,

$$t = \frac{m}{3\pi d\mu} \log_e V_0 = \frac{d^2 \rho}{6\mu} \log_e V_0$$

where ρ is the density of the particle.

The above equations, however, are only true approximately Stokes' expressions apply to smooth spheres and not to irregularly shaped particles. Also, if the diameter of the particle is much less than the mean free path of a gas molecule, the expression for the frictional resistance is not $3\pi d\mu v$ but this quantity divided by $1 + \frac{2}{3}\alpha L/d$ where L is the mean free path of a gas molecule and α is a constant depending on the nature of the particle and its form.

If, then, particles of dust enter the highly rarefied upper hydrogen levels of the atmosphere, they will experience very little retardation until they reach that level (about 100 kms. high) at which viscosity begins to increase rapidly to its normal or full value, but then they will be very quickly brought to rest even in spite of their high initial velocity.

Hence none of this dust will penetrate below a certain level in the atmosphere, probably about 60 to 80 kms. high. It will be stopped and held by air viscosity. The moment its velocity falls off the forces tending to separate the oppositely electrified particles will also decrease, and the oppositely charged particles may then neutralize each other. The result will be, as I think, to

(22) See J. Clark Maxwell. *Phil. Trans. Roy. Soc., Lond.* Vol. 156, p 249. 1866.
Also W. Crookes. *Phil. Trans. Roy. Soc., Lond.* 1881. Part II., p. 387. Plate 57. On the Viscosity of gases.

give the highly conductive layer in the earth's atmosphere a tolerably well-defined under-surface determined by the very rapid rate at which air viscosity rises with increasing air pressure. Hence it is clear that when the dust particles reach a certain level their earthward progress will be practically arrested.

Meanwhile the region above this will be left impregnated with the smaller and lighter negative ions which are moving slowly or quickly in directions oblique to the earth's magnetic meridians and winding their way spiral-fashion towards the regions of the magnetic poles. The explanation of numerous astronomical, meteorological, magnetic and atmospheric electric phenomena by the aid of this hypothesis of electrified solar dust projected by light pressure from the sun to the earth has been worked out in great detail by S. Arrhenius, K. Birke-land⁽²³⁾, W. J. Humphreys and others, but time will not permit of any recapitulation of their published conclusions. This solar dust hypothesis seems to be supported by the observations of Newcomb, Yntema, Abbott and W. W. Campbell on the fact that on clear moonless nights the sky sends to us more light than can be accounted for by the sum total of starlight, and that this extra light is notably greater near the horizon than at the zenith, also by the spectroscopic observations which show the green auroral line in all parts of the tropical sky on moonless nights.

28. In addition to this hypothesis of a permanently conducting upper region of the atmosphere we are compelled to postulate that beneath this there must be a region of variable ionisation due to solar light, which is ionised during the day above the level of clouds dust and water-vapour, but more or less dis-ionised during the night.

Dr. Eccles⁽²⁴⁾ has worked out the consequences of assuming an atmospheric region in which ions of molecular mass are present, possibly formed by the action of ultra violet light on molecular groups which are photo-electric. The presence of these heavy ions acts to produce what is in effect a reduction in the dielectric co-efficient and therefore an increase in the velocity of electric waves through the ionised region.

This action may be illustrated by a magnetic parallel. If iron spheres were placed in a magnetic field they would be magnetised, but owing to the reverse action of the free poles the magnetic force in the iron would be less than the force at that point if the iron were not there. Hence the magnetisation produced is not that which corresponds to the external impressed magnetic force, but to the reduced magnetic force.

In the same manner if heavy ions are present in the air the orderly arrangement of them by the impressed field reduces the effective electric force in the space occupied by them, and this is equivalent to a reduction in mean dielectric constant. But the velocity of the wave is inversely as the square root of the dielectric constant, and therefore the wave speed is increased. From this it follows that if there is a gradually increasing density of heavy ions of both signs as we rise higher in the atmosphere, there will throughout that region be a gradually increasing electric wave velocity with height, and therefore an effect which has been called *ionic refraction* in virtue of which the higher levels of a plane electromagnetic wave advancing over the earth will advance more quickly than the lower parts. Hence the wave track will follow round the earth's curvature and an obliquely rising ray may even be brought down again to earth by an action resembling that of an inverted mirage.

The very complicated phenomena connected with freak signalling, the great effect on signal strength of the sunset and sunrise periods, the curious anomalies in the difference between daylight and night-time radio transmission for various wave length and variation in range between north-south and east-west transmission, have all received certain plausible explanations on the theory of a variable ionisation by sunlight of the atmosphere, and its irregularities at the bounding surface of the earth shadow cone as it sweeps through the atmosphere. The atmospheric ionisation at this surface will tend to become "patchy," and will therefore bestow a certain increased opacity and increased reflecting power on that region for electric waves just as small air bubbles in water give it a certain opacity for visible light.

The general increase in range of radio communication by night is accounted for on this theory as due to partial removal

(23) See *Recent Physical Research*, by David Owen (Benn Bros. Bouverie Street, London).

(24) W. H. Eccles. *Proc. Roy. Soc., Lond. A Series*, Vol. 87, p. 81, 1912. Also *The Electrician* September 27th, 1912.

of the ionic refraction which in the daytime brings the ray down again to earth at ranges less than that due to the guiding properties of the permanently ionised higher layer.

On the other hand, there are curious exceptions to this in the case of certain long-wave transmission. Marconi ⁽²⁵⁾ long ago pointed out that with certain wave lengths from 5,000 to 6,000 metres transatlantic radio signals are often stronger by day than by night. These anomalies and others recorded by Dr. Eccles ⁽²⁶⁾ seem, however, to meet with reasonable explanations on the ionic refraction theory.

On the other hand, our difficulties are great in bringing these hypotheses to critical test. The atmospheric region in which the phenomena takes place is far beyond the reach of our meteorological sounding balloons or possibilities of testing the actual ionic distribution. We can only, therefore, patiently continue to collect the facts and trust to cautious inductive reasoning and observations to give us the true interpretation of them. All the phenomena seem, however, to point to the existence of three superimposed layers in the atmosphere: one, the higher beginning perhaps above 80-100 kilometres' height, which is permanently ionised with negative ions.

The other, the middle, which has in part variable ionisation depending on the position of that part with regard to the sun.

The third or lower level has a relatively small ionisation, but electromagnetic waves travelling in it may have their energy considerably affected and reduced by the nature of the earth's surface over which they are moving. Powerful absorption is caused by some soils and by vegetation for certain wave lengths.

IX. RADIOTELEGRAPHIC DISTURBANCES BY NATURAL WAVES.

29. From the earliest days of long-distance wireless telegraphy the difficulties in reception due to vagrant or natural electric waves and atmospheric electric discharges passing down the receiving aerial have been the bane of the wireless telegraphist. These waves create sounds in the telephone in aural reception which often drown out completely the signal sounds and make false records in the case of printing or photographic reception. In the case of

telephone reception, these noises have been classified into (i) rattling or grinding, (ii) hissing, (iii) clicking or snapping, and (iv) crashing noises. These two last seem to be associated with thunderstorm conditions. Having regard to the fact that the positive atmospheric electric potential gradient of the earth increases at the rate of about 100 volts per metre of ascent, roughly speaking, it is not surprising that aerials several hundred feet high may be traversed by quite large currents due to this cause alone which may utterly swamp the feeble signal currents. The strength of a signal or noise in the telephone is generally estimated by its "audibility," and this is measured by ascertaining the resistance S of the shunt which must be put across the telephone of resistance R just to render the sound inaudible to a normal ear. The audibility A is given by the expression,

$$A = \frac{R + S}{S}$$

Hence the audibility is unity for a just audible sound. We can in this way measure the audibility of a signal on a background of disturbing noise, and a readable signal is generally obtained if the ratio of signal audibility to stray audibility is more than 25%. Owing to the serious extent to which these strays hinder regular reception, especially at certain times of the day and year, an enormous amount of attention has been given to their study and to the problem of eliminating them. They are most troublesome in the summer and during the night, and more severe in tropical than in temperate climes. Even in our latitudes they hinder reception at times immensely. Dr. L. W. Austin has stated that receiving at Washington, U.S.A., with a simple loop aerial from high power radio stations in Europe with aerial sending currents up to 300 amperes, signals were unreadable for about 2,000 hours a year. In tropical countries over long-distance circuits the power required to get a signal through may be often from 6 to 8 times that which must be used at favourable times, and there are short periods when signalling is absolutely impossible. Having regard to the effect such interruptions have upon the earning power of a commercial station or upon certainty of communication in time of war or other urgent occasions, the problem of elimination of strays is perhaps the most important of all the practical questions connected with long-distance wireless tele-

graphy. It has been the subject of countless patents already. Early attempts went on the supposition that the strays were highly damped vagrant waves or had particular frequencies and could be eliminated by giving the receiving system a very pronounced resonance and making it a so-called stiffly-tuned circuit. These methods had a very limited application, for the reason that any impulse given to the receiving aerial sets it in electric vibration with its own natural period. Then, again, a number of inventions depend upon the peculiar properties of certain detectors, such as crystals and thermionic valves, in limiting the current which they pass or rectify. One most practically useful discovery was that by giving to the spark or wave train in the case of spark systems or to the beats in the case of C.W. heterodyne reception a regular frequency of 500 or 600, thus imparting a rather shrill musical sound to the signal, the ear could much more readily fasten attention on it even against a background of irregular but louder noise due to atmospherics.

Another interesting discovery was that of the subterranean or submerged horizontal collecting wire. If a pair of equally long wires are submerged a foot or two under water or buried in damp soil, with a suitable detector at the junction, it can receive from distant stations lying in its own direction, provided we use a two-stage thermionic amplifier in the centre. The optimum length of the wire is about equal to the wave length, but depends to some extent upon the capacity per unit length of the wire used. Such a buried or submerged aerial is largely immune from stray disturbance. The remarkable thing is that reception is far better when the wire is laid in water or wet soil than on the surface of the dry ground. Although the signals received on a buried wire are much weaker than on an aerial wire or vertical loop, the former has the great advantage of directivity and stray elimination.

30. By the combination of a frame or loop aerial with a ground or water wire it is possible to construct a receiving system which is somewhat superior to an ordinary aerial wire in its immunity from stray disturbances⁽²⁷⁾. Another method, claimed

by Mr. Roy A. Weagant⁽²⁸⁾, of the Radio Corporation of America, but really due, I think, to Mr. Franklin, of the British Marconi Company, depends upon the use of two loop aerials with planes vertical and in line with the sending station. These two loops are tuned with capacities and inductances for the wave length to be received and connected in opposition through a coupling circuit with the receiving circuit. The difference in phase of the received currents in these two loops creates the signal, and it has been claimed that by this double loop aerial the stray disturbance is greatly reduced. Mr. Weagant explains this action by the hypothesis that the "grinders" type of stray most prevalent in warm seasons and in the afternoon and evening come down vertically from above. Dr. L. W. Austin disagrees with this view, but there are some reasons supporting Weagant's opinion.⁽²⁹⁾ Austin has recently tested four methods of stray elimination at the United States Naval Radio Research Laboratory, U.S.A., viz.:—

- (1) The Weagant double loop system used at Lakewood, New Jersey, U.S.A.
- (2) The Hoyt-Taylor loop and grounded wire system at Belmar, New Jersey, U.S.A.
- (3) The U.S.A. Naval Research Laboratory system used at Anacostia River, Washington.
- (4) The Otter Cliffs system used at the Naval Station, Maine, U.S.A.

Dr. Austin has stated that with any of these four systems the time during which signals from high power radio stations in Europe are unreadable at Washington, U.S.A., was reduced from 2,000 hours per year to less than 100.

Without some such stray elimination the period of time during the summer months in which these European stations were readable at Washington, U.S.A., was for more than 6 or 7 hours out of the 24. It is probable, however, that rather too favourable an opinion has been given of these devices.

In an interesting paper on the nature and elimination of strays by Dr. C. J. de Groot⁽³⁰⁾ in 1917, he mentions the use of

another method of stray elimination devised by M. Dieckmann, which consists in surrounding the vertical aerial with a sort of cage formed of horizontal wires, these wires being earthed in a particular manner so that the cage is out of tune with the aerial. It is claimed that this cage shields the aerial from all those electrostatic disturbances which are caused by electrified clouds or normal atmospheric potential variations, but allows the aerial to receive the signal waves of which the electric vector is perpendicular to the shielding wires.

de Groot states that this Dieckmann cage is effective in tropical climates in cutting out hissing and rattling telephone noises due to certain strays, but did not exclude clicks due to lightning discharges.

31. Dr. de Groot made an immense number of observations on stray strengths at various hours of the day and months of the year about 1916 in the Dutch East Indies, and prepared diagrams showing the mean stray strength for various hours for each month of the year. From these he prepared a diagram giving the hourly stray strength during the day averaged throughout a year. The results were plotted as a rectangular co-ordinate curve with stray strength shown by the height of an ordinate whose abscissa was the hour of the day by sun or local time. The most interesting result, however, was obtained when this

average stray strength was plotted as a polar diagram for each hour, the radio vectors being 15° apart. (See Fig. 7.)

If we suppose ourselves to look down on the earth from above the North Pole, then a vertical aerial at the Equator would revolve counterclockwise and the Polar diagram of stray strength, if plotted round the diagram, would be a closed curve which has a minimum radius at about 10 a.m. or so and a maximum radius at about 10 p.m. The radii of the curve during the day are smaller than that during the night.

The diagram then suggests at once the question: Why are the strays in general more numerous and stronger during the night than the day?

We have seen that there must be a certain intermediate but high level region in the atmosphere in which the gases are ionised by the ultra violet sunlight during the day, but re-combine again during the night. This region lies beneath the permanently ionised layer. In this permanently ionised layer there are drifting collections or masses of positively electrified and negatively electrified solar dust. If these masses are drawn together by their electric attractions or commingled, it is highly probable that electric re-combinations will occur, which would generate electric waves. Suppose, then, that we assume the origin of a certain part of the strays to be in the upper permanently conductive layer of the atmosphere, these natural waves would find a certain obstacle to their downward transmission in the conductivity produced by the ionisation of the middle layer of the atmosphere by day. But at night-time this middle layer ionisation largely disappears and the natural electric disturbances in the upper layer would more easily find their way down to the earth. In other words, there would be a more unhindered access for the strays to descend. Hence in the night-time they would be more numerous and apparent in the effect they produce on receiving appliances.

The view that the strays which produce continuous rattling or grinding noises in the telephone have their origin in the high level permanently conductive layer of the atmosphere was also put forward by Dr. de Groot, and he has employed ingenious arguments to obtain an estimate of the height of this layer, which he places at between 180 and 200 kilometres.

FIG. 7.—Diagrams showing the mean diurnal variation of stray intensity. (C. J. de Groot.)

These estimates must, however, be brought into comparison with the observations which have been made on the heights of the Aurora. Störmer has made precise measurements of the parallax of the beams and arches of aurora by photographic observations at places connected by telephone, and found, out of 150 observations, that the lowest occurred at 40 kms. and the highest at 260 kms. Much, however, depends upon latitude and the height of the region ionised by cosmic dust may be greater at the terrestrial equator than at the poles. The whole subject is of great importance in connection with meteorology and terrestrial magnetism, and invites the co-operation of physicists, astronomers and meteorologists, as well as radio-engineers.

The matter is, however, of such immense practical importance in radiotelegraphy, that improvements or inventions connected with it are generally kept as carefully-guarded secrets, at least, for some time. Senator Marconi spoke recently of inventions due to himself and technical staff which promise a great advance in overcoming the interruptions of service due to strays, but details are at present withheld.

Time does not permit any more extended reference to the work of Marconi, Round and Tremellen, Franklin, Austin, Hoyt-Taylor, de Groot, Fessenden, Weagant, and many others who have devoted great attention to this extremely important matter during the last two decades.

The problem of eliminating altogether the effect of strays on the receiver is at present the paramount one in long-distance wireless telegraphy, as they are then a source of far greater difficulty than in short-distance working.

X. IS THERE AN ÆTHER ?

32. In bringing to a conclusion this brief and imperfect sketch of the progress in 21 years of long-distance radiotelegraphy, it is impossible not to give a moment's attention to a question which is fundamental in connection with it. The starting-point for all this work was that great product of James Clerk Maxwell's incomparable genius, the electromagnetic theory of light. It postulated a universal medium, identified with the luminiferous æther of Fresnel and Young, in which the effects we call magnetic flux and electric strain are propagated as a wave motion. It was in the attempt to verify certain deductions from Maxwell's

theory that Hertz was led to give us the experimental means of producing Maxwell's waves. The researches of some of the world's most notable scientific investigations provided the basic facts on which equally distinguished inventors have built up the splendid edifice of modern radiotelegraphy. But of late years facts have been discovered which seem irreconcilable with the original form of Maxwell's theory and with the previously held view that radiant energy is uniformly spread over its wave front and emitted continuously by a radiating body. Observations on the energy aspects of ionisation by light, the distribution of energy in the spectrum and of specific heats, seem to suggest that the energy of a light wave is concentrated along certain lines or points on the wave front surface and emitted and absorbed in certain finite units called quanta. Moreover, no experiments yet devised have enabled us to determine any motion of this hypothetical æther relatively to the earth or any other moving matter. If the electromagnetic medium exists as a stagnant æther in space, and if the earth moves through it like an aeroplane through the air, then what may be called an æther wind is blowing through our laboratories with a velocity in some directions and at some times of at least 30 kms. per second. The classical Michelson and Morley experiment was designed to detect this æther movement if possible by its effect on the time taken for light to move a certain distance there and back along and across this æther wind. But, to the surprise of physicists, the result showed an absolute equality in these times, quite different from the result which would have been found if we had employed waves of sound in moving air. Other experiments by Lodge, Trouton, Rayleigh and Brace gave similar null results.

Certain mathematical physicists have therefore declared, as Professor Eddington did lately at Edinburgh, that "the æther must now be regarded as an idle hypothesis unsupported by experiment and giving explanations of nothing."

Others, on the other hand, consider that the facts of physics do not justify this conclusion.

We know that light not merely takes time to travel and brings intelligence of distant events, but conveys energy in enormous quantities from place to place. A cubic mile of space filled with sunlight

near the sun's surface contains at least 300,000 foot-tons of energy, enough to hurl 20 tons over the top of Mont Blanc.

Energy comes in vast amounts from the sun to the earth and occupies $8\frac{1}{2}$ minutes in the journey. We then ask: How, and in what manner, is that energy stored up and conveyed *after* it has left the sun and *before* it reaches the earth? Again, a light exerts a pressure upon objects on which it falls. The sun, by its radiation, presses the earth and other bodies away from it, and the reaction presses the sun back. In what, and where, does this stress exist?

Radio-engineers who regard in all cases the energy aspects of a problem may be content to take the guidance of mathematicians on the relativity of our ideas of space, time, velocity, acceleration and the other concepts of kinematics and geometry, but they will hardly be willing to surrender the opinion that space is not mere emptiness or a *vacuum*, but is a *plenum* possessed of very definite powers of energy storage and energy transmission. It is clear, however, that some great enlargement of our views about the electromagnetic medium is necessary to make them embrace new knowledge. The aether may be elusive, as elusive as the Scarlet Pimpernel in Baroness Orczy's famous story, but it is the aim and duty of physics to find the generalizations which will harmonize observed facts and explain them all by one consistent theory. Some of these difficulties can be minimised if we return to Faraday's idea that light, and therefore electromagnetic waves, are vibrations propagated along lines of electric force. This conception has been mathematically developed at great length by Sir Joseph Thomson and expounded by Dr. Norman Campbell. Since lines of electric force proceed from electrons, positive and negative, and on the Faraday-Maxwell theory have tension (T) and mass (M) per unit of length, the velocity of propagation along them is $c = \sqrt{T/M} = 3 \times 10^8$ metres per second. The electron may therefore be regarded as the centre of a radiating system of lines, I call *electrolines* for shortness, along which vibrations are propagated when the electron vibrates.

In this sense, then, every source of radiation makes its own aether. If a vibration proceeds from a source and is reflected back by a mirror, the vibrations run out along the electrolines proceeding from the electrons in the source and return along

electrolines proceeding from electrons in the mirror. If, then, a source and a mirror are rigidly connected together, the time taken by a vibration to run from the source to the mirror and back again, as in the Michelson-Morley experiment, will be quite independent of the manner in which the system is being moved about.

From this point of view, all space is filled with interlacing electrolines and has a fibrous structure. But even if such an hypothesis may explain some facts, it probably raises more difficulties than it meets. We await some second Newton or Maxwell whose genius will dissipate the clouds that still shroud in darkness the structure of space and the nature of radiant energy.

Meanwhile the radio-engineer deals with phenomena which lie on the borderland of our finite knowledge and our infinite ignorance. In 21 years he has been able so to control the subtil energies of Nature that he has made of the world one vast auditorium in which long-range radio stations now speak simultaneously to every place on the habitable earth at which a suitable receiver is placed.

Our hope and desire is that these enlarged powers of communication may be exercised for the benefit of humanity at large and promote peace and goodwill between all the nations which make up the family of mankind.

DISCUSSION.

THE CHAIRMAN (Mr. Alan A. Campbell Swinton, F.R.S.), in proposing a hearty vote of thanks to Professor Fleming, said the lecture that had just been delivered was one of the most interesting and memorable lectures that had ever been given in the Hall of the Society. Professor Fleming had devoted his life to electrical matters, and during the latter half of his life he had dealt particularly with those electrical matters that appertained to wireless telegraphy. He thought Professor Fleming was the greatest publicist in the world in the way of writing books on the subject, and in the present year the Royal Society of Arts conferred upon him the highest honour it was able to award, i.e. the Albert Medal, for his invention of the thermionic valve, which had done so much to promote the extension of wireless telegraphy. It was now 21 years since long distance wireless telegraphy had been invented, and Professor Fleming had given a most interesting account of its coming of age. The Society and the meeting were honoured by the

presence of the one individual who had done more than anyone else to produce the wonderful results referred to in the lecture. He alluded, of course, to Senatore Marconi, who, like Professor Fleming, had received the Society's Albert Medal, and he would ask him to second the vote of thanks to Professor Fleming.

SENATORE G. MARCONI, G.C.V.O., LL.D., D.Sc., said it gave him great pleasure to second the vote of thanks to Professor Fleming for his extremely interesting lecture, which he had very appropriately entitled "The Coming of Age of Long Distance Radiotelegraphy." Those present that evening had had the pleasure of listening not only to Professor Fleming's clear and scientific exposition of the progress and development of long distance radiotelegraphy, but also to the brilliant views which he had put forward to account for some of the still unexplained facts of wireless telegraphy. Personally he was particularly interested in the hypothesis that the apparent bending of electromagnetic waves round the curvature of the earth might be due to their reflection from a more or less sharply defined upper layer of the atmosphere—containing highly ionised dust flung off by light pressure from the sun. Not only was that matter of practical and scientific interest for transmissions over what he might now call moderate distances, i.e., distances of a quarter of the way round the world, but it possessed a still greater interest with regard to the problem of communicating with places close to the Antipodes. The relative facility with which signals were now transmitted from England to Australia seemed to prove that there was something in the idea of the waves bending round and concentrating at places near the Antipodes. Sixteen years ago he expressed that view in a lecture which he delivered before the Royal Institution, when he showed a model of the globe and tried to explain how he thought the waves might help each other if in proper phase, or, in other words, concentrating at places at the Antipodes or the transmitting station. If that was true, it might be a fact that messages could be sent to the Antipodes with a very much smaller amount of energy than was necessary to send them to places at shorter distances. Not only was wireless telegraphy indebted to Professor Fleming for his numerous and valuable contributions to the theoretical side of the subject, but personally he wished to put on record once more Professor Fleming's most valuable co-operation in the early design of long distance transmission plants at Poldhu and other stations, and, with regard to the practical side of radiotelegraphy in general, much gratitude was due to Professor Fleming for his invention of the Fleming thermionic valve, which was perhaps one of the most important contributions to the practice of long

distance communication. The improvements made to that arrangement not only constituted it the most practical and the most sensitive receiver, but also enabled it to be used for the transmission of messages as an oscillation producer which, in his opinion, was the most practical and efficient now in existence. He need not say how fascinating the possibilities of long distance radiotelegraphy were and how every day they became still more fascinating. He was still busily engaged in working on the subject, which had also attracted the attention of a great many other people all over the world. In that connection he might say that his contact with so many phases of radiotelegraphy had lately given him the impression that, so far as the practical side of long distance communication was concerned, those who were working on the subject had perhaps rather got into a rut. If there was found to be no other, the views at present held might have to be changed, but he hoped that whatever was ascertained would go to improve the fascinating application of science with which the lecture had dealt. He was very happy to second a warm vote of thanks to Professor Fleming for his extremely interesting and brilliant Lecture, a vote of thanks which had been so ably proposed by the Chairman, and he wished to assure Professor Fleming how deeply everyone present had appreciated the privilege of listening to the lecture.

The resolution was carried unanimously.

PROF. J. A. FLEMING, M.A., D.Sc., F.R.S., in reply, said he was particularly grateful to the Chairman for his remarks and also to Senatore Marconi for honouring the meeting by his presence and for honouring him personally by seconding the vote of thanks.

The meeting then terminated.

NOTES ON BOOKS.

RECOLLECTIONS. By Sir Charles W. Macara, Bart. London, New York, Toronto and Melbourne: Cassell & Co., Ltd. 7s. 6d. net.

A friend, herself a daughter of the manse, once confided to the writer of this note, that it was her ambition to write a book called "Sons of the Manse," in which she hoped to demonstrate how much the British Empire and the world at large owed to this admirable race. If the book is ever written, the name of Sir Charles Macara ought to hold an honoured place in it. Born in the manse of Strathmiglio, Fifeshire, in 1845, with nothing but his own energies to depend upon, Macara, at an early age, reached a responsible position in connexion with the representation in Manchester of one of the super-firms in Scotland, and he soon came to be regarded as the head of the cotton industry, which, after agriculture, is the most important industry of Great Britain.

In the work before us, Sir Charles looks back from the comparative leisure of retirement, over the principal events of an extraordinarily useful and busy life, and he selects a few of the most interesting for review. If he had nothing to his credit beyond his share in carrying through the Brooklands Agreement of 1893, Sir Charles would have deserved well of his country. Not only did this Agreement endeavour to substitute in the cotton industry a reign of reason for a reign of force, and to tie both employers and employed to rules which would make it as difficult as possible to enter upon either a lock-out or a strike; it did a great deal more than that: it dealt with the question of the workers' right to a "say" in industry—a question that was not settled by the railways till twenty years later.

Sir Charles's account of the battle over the Brooklands Agreement is of extraordinary interest. The representatives of the two sides, employers and employed, met at Brooklands, a suburb about seven miles from the centre of Manchester. The conference began at three o'clock on March 23rd, 1893. Six times during its course, the two sides broke away from each other. Happily there was one man on each side determined to bring the matter to a satisfactory issue—Sir Charles Macara, representing the employers, and James Mawdsley, leader of the employees. Thanks to the efforts of these two, agreement was at last reached at five o'clock in the morning of March 24th; and as a result, for the next twenty-one years there was only one strike regarding wages that affected the whole industry, although before this time, the cotton trade was known as the cock-pit of industrial strife.

Another feather in Sir Charles's cap was the establishment of the International Cotton Federation. He was its President from its formation, at Zurich in 1904, until the year 1915. It would be impossible to over-estimate the value of the work which the Federation has done in drawing together the cotton-using countries of the world. Annual conferences were held in Germany, Austria, France, Italy, Belgium, Spain, Portugal and Holland, and international delegates visited America and Egypt. "The movement," writes Sir Charles, "was prosecuted with great vigour until the war interfered with its operations, and perfect harmony characterised its deliberations."

A further international movement which owed not a little to the services of Sir Charles was the establishment of the International Institute of Agriculture. He was among the first to realise the greatness and importance of the scheme proposed by David Lubin, and he threw himself whole heartedly into the task of realising Lubin's idea. The International Institute of Agriculture is now a *fait accompli*, and the bulletins which it issues are regarded as of first rate value wherever scientific agriculture

is practised. "Since their formation, in 1904 and 1905, respectively," to quote Sir Charles again, "these two international movements have been in continual co-operation . . . and have demonstrated that work for the benefit of mankind may be done and will be done quite readily by men drawn from numerous countries, who, in the doing of it, willingly sink their distinctions of nationality."

Want of space prevents our referring at any length to Sir Charles's magnificent work in the war and in the coal crisis of this year, but a word must be said of his work for the National Lifeboat Institution. In 1891 he issued an appeal on its behalf, and he started the eminently successful movement known as "Lifeboat Saturday." Mainly as a result of his labours (which were merely a *parergon*, an addition to his ordinary day's work), the income of the Institution was raised from £42,000 in 1891, to £137,000 in 1919.

The life of Sir Charles Macara, with its generous, unselfish and finely practical aims, should serve as an inspiration to the young business man.

OBITUARY.

THE EARL OF HALSBURY—The veteran lawyer and statesman, Lord Halsbury, died in London, on December 11th, at the great age of ninety-eight. Coming of an ancient Norman line, he was the son of Dr. Stanley Lees Giffard, a contributor to the *Quarterly Review*, and for a very long time Editor of the *Standard*, in whom it was said departed the last of the school of Georgian political writers who brought so great a fund of learning to the press.

Lord Halsbury was not only the longest lived of English Lord Chancellors, but he held the Great Seal for about seventeen years, a term exceeded by only two of his predecessors Hardwicke and Eldon.

Educated at Merton College, he was called to the Bar in 1850, and soon achieved a reputation as an advocate in criminal cases, though, unlike some of his brilliant contemporaries at the Old Bailey, he also engaged in civil work. He took silk in 1868 and about this time distinguished himself by his powerful defence of Ex-Governor Eyre. In 1875, in spite of his not then being a member of the House of Commons, he was appointed Solicitor-General. He did not succeed in obtaining a seat in Parliament until 1877, when he was elected for Launceston, and at last was able to join his colleagues on the Treasury Bench. He continued to represent Launceston until 1883, when he became Lord Chancellor in Lord Salisbury's first Administration. He filled the same office in four Governments. It has been said that his name will always be connected

with one of the greatest reforms, that enabling prisoners to enter the witness-box and give evidence. In his later years he devised and supervised the issue of "The Laws of England." He was President of the Royal Society of Literature, Senior Grand Warden of English Freemasonry and High Steward of Oxford University. He was a Life Fellow of the Royal Society of Arts, having been elected as long ago as 1866. He served on the Society's Council as a Vice-President from 1894 to 1898.

THE RUBBER INDUSTRY OF BOLIVIA

The rubber industry, one of the most important in Bolivia, is centred in the Amazonian region of the Republic. Though the first rubber was taken out along the Mamore in 1864 and production amounted to 2,000 arrobas (of 25.36 pounds each) by 1878, the development of the industry on a large scale dates from the eighties. Much of the rubber country was explored about that time by an American. The year 1882 was a great one in the history of the industry, but the depression caused by the outbreak of swamp fever, which followed the floods of 1886, caused a temporary setback. With the rapidly increasing demand for the product, rubber hunters poured into the Beni and Mamore districts, and numerous companies were organized to exploit the resources of those regions. The production of 1898 was double that of the previous year and in 1900 reached the highest figure attained until 1911. However, the best returns from the business were during the boom years from 1909 to 1911, during which period rubber reached the maximum price of 12 shillings per pound. From that time the decline in the returns was constant until 1915, but the yield of 1917 brought only about two-thirds as much as did that of 1910. By 1917 the East Indian plantations were producing and Amazonian rubber had taken the second place in the world market, at least in so far as quantity was concerned.

According to a report on the industry by the United States Trade Commissioner in Bolivia, rubber is found in the Territory of Colonias and in the four northernmost Departments of the Republic—El Beni, La Paz, Cochabamba, and Santa Cruz. The Beni district has steadily declined in relative importance as its stock of trees has been worked out, and the Territory of Colonias has become the most productive rubber region in Bolivia. Rubber trees are found in large quantities along all the rivers of Colonias, including the Acre, Abuna, Orton, Madre de Dios, and their tributaries. Development in all these districts is comparatively recent, the rubber resources of the Abuna not having been worked until 1904. Most of the gomales, or rubber plantations, of El Beni are along the lower reaches of the Beni and the

Mamore, in the Province of Vaca Diez, and to a lesser extent in that of Yacuma; there are also important fields in the Itenez Basin. The rubber districts of Santa Cruz are located in the Provinces of Nuflo de Chavez and Velasco, and lie mostly between the San Miguel and the Paragua. San Ignacio and Concepcion are the chief centres of the rubber business of this part of Bolivia. The rubber industry of the Department of La Paz is restricted to the Province of Caupolicán, and to a much less degree to those of Larecája, Muncas, and Nor Yungas. The comparatively unimportant gomales of the Department of Cochabamba are situated in the Province of the Chapare in the basin of the river of that name and in the basin of the D'Orbigny.

The highest grade of Amazonian rubber, known as Para fine, is derived from the hevea tree, which stands from 30 to 40 metres (metre 3.28 feet) high and may attain a diameter of a meter or even more. An inferior grade of rubber is extracted from the caucho tree (*Castilloa elastica*). The product is sold on the market as caucho. The caucho trees that are worked are generally from 30 to 50 metres high. Contrary to the procedure used with the hevea, the caucho must be cut down in order to obtain the sap. The rubber known as ceara is extracted from the manicoba tree (*Manihot glaziovii*), which is also found, though not in great numbers in the Bolivian forests.

The rubber trees do not exist in solid stands, but are found scattered throughout the general forest. The belts along the rivers where they occur seldom extend inland more than 10 or 12 miles. The tree prefers low ground in the neighbourhood of swamps and watercourses, where the moisture is retained in the ground throughout the year, and it appears to thrive best on land that is inundated about once every three years.

The methods of gathering the rubber used by the Bolivian *seringueiro*, or extractor and coagulator, are much the same throughout the rubber districts of the Republic, though some improvements have been made in the procedure of extraction during the last few years. Each *seringueiro* or *picador* is assigned an *estrada* of 150 trees, which he is to work. Every day during the season he goes the rounds of his *estrada*, beginning his labours about daybreak. With a long-handled hatchet he makes from 6 to 12 incisions in the bark of the tree as high as he can reach on the trunk, and under each incision he places a tin cup into which the latex or sap flows. It requires about three hours to make this first round of the *estrada*, and after a short rest the *seringueiro* makes a second round of the trees to collect the latex from the cups. He empties the latex into a bucket and carries the proceeds of his morning's work to his encampment for coagulation, which is accomplished by a smoking process.

The contents of the bucket are poured into a basin and the latex poured over a stick which is revolved in the dense smoke produced from hard palm wood or palm nuts burned in a small oven. The latex coagulates rapidly in this smoke and gradually forms a ball, which is taken off when at a convenient size, about 40 or 50 pounds, and placed to dry under a roof of palm leaves. In this way the characteristic Para rubber balls are produced, and an incision will show the layers made by the turning of the rubber during the process of coagulation.

Each day the workman makes the incision on the tree an inch or two lower down on the trunk until the roots are reached, when the tree is left to rest until the next year. Trees are worked continuously during the rainy season of each year for two or three years, and then are not worked for an equal period. The life of a tree which is under exploitation is from 15 to 30 years, largely depending on the care taken in making the incisions. Those made by a careless picador will reach below the bark of the tree and injure its vital parts, thus causing it to die before its natural term of life.

Of late years experiments have been made with the so-called herring-bone system, which is used on the plantations. By this method a knife with a short convex blade just wide enough to enter the bark is used to make a long, vertical incision about 4 feet in length. A number of parallel lateral incisions are then made on each side of and terminating in the central incision. The latter serves as a kind of trough through which the latex from the lateral incisions flows down the side of the tree and out through a small spout into a bucket. This method preserves the tree from the dangers which result from the deep incisions made by the old system in which the hatchet is used.

On the arrival of a consignment of rubber at Manaos or Para, a bolacha or sample ball is cut through several layers with a knife for the purpose of classifying the lot. There are eight classes, according to this preliminary inspection, though the rubber is generally shipped as of two classes. The eight classes are as follows: Fina, fina flaca, entrefina, entre-fina-flaca, sernamby en rama, sernamby virgen, sernamby de caucho, and caucho. However, these are exported to the foreign market as fine or ordinary. The rubber known as fine hard Para is the prime product of the latex of the hevea. Sernamby is second quality rubber, and, though a product of the hevea, it contains impurities which mar its value; it is sometimes made of the residue after the preparation of the fine Para. If rain has fallen in the cups while the latex is being collected, the product will be classified as sernamby. Caucho is the product of the caucho tree and is altogether a lower grade of rubber.

The fact that Bolivian rubber is either classed as Para or Mollendo on the foreign market does an injustice to Bolivia, against which Bolivians have long protested. Amazonian rubber is known to the rubber trade only by the ultimate port of shipment, which is generally either Para, Brazil, or Mollendo, Peru. The rubber from the country about the lower reaches of the rivers is exported through Para, and that from the Beni headwaters is sent out through the Pacific port of Mollendo.

The Amazonian rubber industry, including, of course, that of Bolivia, has been seriously threatened by the rapid development of the East Indian plantations. Though realizing the menace, the South American rubber interests, says the Trade Commissioner, appear to have done little to meet it. A few Bolivian companies have considered the establishment of plantations, and at least one prominent rubber grower has actually planted some trees, but the movement has progressed no further. Meanwhile, owing to their more economical methods, the plantations have rapidly gained control of the world rubber market.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.

- MONDAY, DECEMBER 19.** Mechanical Engineers, Institution of, Storey's Gate, S.W., 7 p.m. (Graduates' Meeting.) Mr. C. Poole, "Worm-gearing," (Yorkshire Branch), Sheffield, 7.30 p.m. Dr. W. H. Hatfield, "Recent Developments with regard to Alloy Steels and their Uses" (North Western Branch) Memorial Hall, Albert Square, Manchester, 7 p.m. Mr. G. Mitchell, "Conveying and Elevating Machinery," 2. Mr. R. E. Knight, "Discharge of Grain Cargoes in the Port of London by Pneumatic Elevators."
- University of London, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C., 4 p.m. Mr. F. W. Twort, "Recent Researches on the Biology of Bacteria." (Lecture IV.)
- British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. T. E. Colcutt, "A Plea for a Broader Conception of Architectural Education."
- TUESDAY, DECEMBER 20.** University of London, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C., 4 p.m. Mr. F. W. Twort, "Recent Researches on the Biology of Bacteria." (Lecture V.)
- Sociological Society, 65, Belgrave Road, S.W., 8.15 p.m. Mr. C. Dawson, "The Life of Civilizations."
- Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m.
- Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Mr. R. Pezzani, "Mauritius."
- Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. C. R. C. Petty, "The Chamonix Valley."
- WEDNESDAY, DECEMBER 21.** Meteorological Society, 49, Cromwell Road, S.W., 5 p.m.
- Geological Society, Burlington House, W., 5.30 p.m.
- Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. A. Dalgleish, "Trade Boards."
- United Service Institution, Whitehall, S.W., 3 p.m. Captain E. W. Sheppard, "German Views on the Marne Campaign."

Journal of the Royal Society of Arts.

No. 3,605

VOL. LXX.

FRIDAY, DECEMBER 23, 1921

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

SEVENTH ORDINARY MEETING

WEDNESDAY, DECEMBER 14th ; Mr. EDWARD DENT, Member of the Council, in the Chair.

The following candidates were proposed for election as Fellows of the Society :—

Chari, N. S. T., M.A., Calcutta, India.

Gibson, Mrs. Marlon Campbell, Perth, West Australia

Gwyn-Williams, Captain R. H., O.B.E., M.C., Balaghat, Central Provinces, India

Hardcastle, Charles Henry, Bombay, India.

Harding, Henry George Alan, F.C.S., North Sydney, N.S.W., Australia.

Lahiri, Purna Chandra, L.M.S., Dibrugarh, Assam, India

Saksena, Ram Bahu, M.A., LL.B., Sabaranpore, United Provinces, India.

Stubbs, Roy Wilson, Karachi, India.

Sturrock, George S., Lahore, Punjab, India.

Watson, Edwin Alexander, Calcutta, India.

The following candidate was balloted for and duly elected a Fellow of the Society :

L. D. Varshnei, Bahjoi, India.

A paper on "Trade with the Netherlands East Indies," was read by Sir Walter Beaupré Townley, K.C.M.G., Minister to the Netherlands, 1917-19.

The paper and discussion will be published in a subsequent number of the *Journal*.

REPRINT OF HOWARD LECTURES.

The Howard Lectures on "Aero Engines," by ALAN E. L. CHORLTON, C.B.E., M.Inst.C.E., M.I.Mech.E., have been reprinted from the *Journal*, and the pamphlet (price 4s.) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2.

A full list of the lectures which have been reprinted and are still on sale can also be obtained on application.

MANN JUVENILE LECTURES.

Under the Mann Trust a short course of lectures adapted to a juvenile audience will be delivered on Wednesday afternoons, 4th and 11th January, 1922, at 3 p.m., by Mr. William Reginald Ormandy, D.Sc., F.I.C., on "Clay: What it is--Where it comes from--and What can be done with it." The lectures will be illustrated with experiments.

Special tickets are required for these lectures. A sufficient number to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply to the Secretary at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

CASES FOR JOURNALS.

Cases for keeping the current numbers of the *Journal* are now obtainable. They are in red buckram, and will hold the issues for a complete year. They may be obtained post free, for 7s. 6d. each, on application to the Secretary.

BINDING COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their annual volumes of the *Journal*, cloth covers can be supplied, post free, for 2s. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES AND INDIAN SECTIONS

(Joint Meeting).

FRIDAY, NOVEMBER 25TH, 1921.

BRIG.-GEN. LORD MONTAGU OF BEAULIEU, K.C.I.E., C.S.I., in the Chair.

THE CHAIRMAN, in introducing the author of the paper, said that Mr. Ashbolt came from almost the furthest part of the British Empire, measured in miles, from where he now stood, and, therefore, appreciated on that account the necessity for more rapid communications between the mother country and the great Dominions over seas. Last summer, when the question of airships and airship personnel was being dealt with at the Imperial Conference, and afterwards, he had been one of the keenest supporters of airships; and to Mr. Ashbolt belonged a great deal of the credit for such concessions as had been obtained on that occasion, although they had not, at that moment, seemed to amount to much. He was sure that Mr. Ashbolt would send his audience away with the firm conviction that the British Empire could not afford from any point of view to be left behind in the development of aviation. It was a painful thing to have to admit, but there was no doubt that other nations, like the United States, Japan, France and Germany, and even Spain, were doing far more in regard both to short distance and long distance aviation than we were. That was quite wrong for a great Empire, and especially wrong for the British Empire, which had, at any rate at the end of the war, attained a pre-eminent position in aviation.

The paper read was:—

AN IMPERIAL AIRSHIP SERVICE.

By A. H. ASHBOLT,
Agent-General for Tasmania.

The announcement of the British Government that they had decided to cut the airship out of the scheme for defence and to limit aerial military operations to the aeroplane was not altogether unexpected, but the subsequent intimation that unless satisfactory arrangements could be made for the utilisation of the existing ships and plant in Great Britain for commercial purposes they would be destroyed and the entire service and organisation disbanded came as a great shock, not only to the personnel of the service in question, but to the general public. Further, no suggestion was made to utilise the ships

and organisation for Imperial developments, this phase of the matter having apparently been overlooked or not taken into consideration. On reading this notification its Imperial possibilities struck me immediately, and I interviewed the Right Honourable Winston Churchill, Secretary of State for the Colonies, and Sir James Stevenson, whom Mr. Churchill called into consultation. The result was the submission on May 9th last of a proposal, addressed to the British Government, to initiate an Imperial Service, and after further negotiations, the Air Ministry published a communication, No. 675, on May 31st setting out the terms and conditions under which they were prepared to offer the fleet of ships, material and information acquired. Now, to acquire the existing fleet, sheds, plant and stores, together with the knowledge gained by our airship personnel, cost the British public about £40,000,000, so that if we break up the plant and organisation with its most important technical staff, etc., and restart in say four or five years to rebuild the existing fleet of ships, sheds, plant, accumulate the same stores and re-acquire the present knowledge of the existing personnel, would cost about £12,000,000. This fact, plus its use as a Naval auxiliary and the Imperial necessity for more rapid communication between the various parts of our Empire, and also the further fact that the British Empire is so advantageously placed over so much of the globe that we can if desired build our aerial stations so as to refuel on our own soil throughout the length and breadth of the suggested routes, makes the decision inexplicable and entirely lacking in that vision which should characterise the judgment of our statesmen.

No truer summary of the position could be given than that of the Prince of Wales in his speech at the annual dinner of the Royal Colonial Institute, where he drew an analogy between the spreading of the Roman Empire and its subsequent disintegration through insufficient communications. Are we to stand still and take no notice of the evolution going on around us? Major-General Sir F. H. Sykes said the other day:—"The evolution of civilisation is first the phase stretching back into the "roadless mists of unrecorded time—"their threads of intermittent barter—the "era of roads which gradually linked the "important areas of the Roman Empire—

"The epoch of the more economical water-way with Venice as the pivot—The age of ocean sailing which brought England to the fore—Then as man was becoming used to the great possibilities indicated by the Elizabethan adventure, came the 'crescendo of iron, of steel and of steam.' Are we to say that the steamships of to-day, magnificent as they are in every respect, mark the final means of personal communication between the component parts of our Empire? And yet that is what we contemplate if the decision of the British Government is carried out. Its possibility can only be brought about by the mental stagnation or indigestion which seems to be one of the unfortunate aftermaths of the Great War. To revivify that mentality is one of the objects of this paper, and for this purpose I propose dealing under different headings with the project to launch an Imperial Airship Service.

First, I would like to remind you that in 1913 airships were transferred to the Admiralty, but it was not until 1917 that any construction programme was commenced. In the summer of 1918 the Admiralty contemplated a programme which provided for the building of 16 rigid airships of R 33 class or better. In 1919, however, before these vessels were completed, the control of airships passed from the Admiralty to the Air Ministry. At the time of the transfer it was arranged that the Admiralty requirements would be met by maintaining one airship in commission and building a new airship every two years. Subsequently the decision to discontinue entirely airship operations was come to, and looking at the position from the point of view of a Government anxious to reduce expenditure and cut out everything but actual necessities, I can to some extent sympathise with the decision, but I am strongly of the opinion that such a saving is not commensurate with the loss by the Navy of their airships nor with the loss of closer Imperial relations which an Imperial service such as I suggested, would establish. To me it seems that all that was required to develop its Naval and Imperial possibilities was a reorganisation which would have permitted experiments and developments of airships on these lines instead of letting them continue as part of the Air Ministry, which was necessarily dominated almost entirely by military interests. It was, and is, a curious fact

that so many of the real heads controlling aviation matters have never made themselves conversant with the actual detail of airships, and in many instances have not even had a flight in them. If ever there was a case in official circles of the "unwanted child," they had it in airships. Banded from pillar to post with no definite constructive policy and no one in high command with sufficient interest to carry out the proposals of the late General Maitland and the enthusiastic group of officers banded with him, or to insist upon experiments on consecutive and developmental lines meant that the work done was of a desultory character at a cost altogether out of proportion to the visible results achieved. Admitted that members of the personnel were acquiring considerable knowledge in connection with the flights from the mast at Pulham, there was no definite attempt at flying between termini. All the work centred round the one mast and the knowledge acquired was apparent to but very few. Admitted, again, that there is very little real difference in flying from the mast-head at Pulham and re-berthing some hours later, from flying from Pulham and re-berthing at the Riviera or some other Continental centre, there is this fact that in the first case no public results are achieved, whilst in the latter a distinctively definite object has been gained. The Right Honourable the Prime Minister for Australia said on one occasion:—"I do not want to fly round 'a saucer. Fly me to a point on the journey 'to the Antipodes and I will then agree 'that you have made a definite advance 'in aerial navigation.'" Some eighteen months was, unfortunately, lost in what might be termed desultory flying at an inordinately high cost.

The result of my proposal and subsequent negotiations was that the matter was then placed upon the agenda paper for consideration at the Imperial Conference of Premiers called for the end of June, 1921. The Imperial possibilities of such a service were then for the first time realised by the Press and British public, the former, particularly *The Times*, giving very great publicity to the suggestion, which also received considerable favour from the public in the Overseas Dominions, especially Australia, New Zealand and South Africa. At the Conference the question was thrashed out at a great length, but before discussing definite proposals the Premier's Conference

referred the matter to a special commission comprising the following individuals:—

Captain the Rt. Hon. F.-E. Guest, C.B.E., D.S.O., M.P., Secretary of State for Air (Chairman).

Lord Gorell, C.B.E., M.C., Under Secretary of State for Air.

Air-Marshal Sir H. M. Trenchard, Bt., K.C.B., D.S.O., Chief of the Air Staff.

Major-General Sir F. H. Sykes, G.B.E., K.C.B., C.M.G., Contoller-General of Civil Aviation.

Sir G. L. Barstow, K.C.B., representing H.M. Treasury.

Sir James Stovenson, Bt., representing the Colonial Office.

J. H. Lovell, Esq., representing the India Office.

Sir Ross Smith, K.B.E., representing Australia and New Zealand.

Colonel the Hon. H. Mentz, representing South Africa.

L. V. Meadowcroft, Esq., Secretary.

This commission reported under date of July 26th, 1921, *inter alia*:—"Although 'the existing fleet of four airships when put 'in commission will enable a scheme of 'Imperial communications to be begun, 'it is insufficient to enable a complete 'scheme to be developed.' The report then goes into the question of developing the service by (a) the Governments concerned, or (b) commercial enterprise alone. Estimates showing that any experimental service initiated must be at least for a period of two years are also given by this Commission. No question whatever is raised as to the unsuitability or impossibility of establishing such a service; its practicability and Imperial necessity are accepted by them without qualification or argument. The report confines itself largely to the financial side of the question, and it is entirely on this point that the question of the establishment of the service, and British supremacy in the commercial airways of the world, is at stake. The outstanding question is how is the necessary money to be found in these days of stringency to provide for a period of at least two years, during which the commercial possibilities and the Imperial character of the service can be tried out? In my opinion Government assistance is necessary. In pre-war days one could always rely upon obtaining the support of a number of what might be termed commercial adventurers in the interests of themselves and their Empire, but to-day

the money market is such that this free money is not now available. However, the spirit of adventure still rises in our breasts and even under to-day's chaotic financial conditions the money required can be obtained provided the Governments concerned give the service practical support by the diversion of a portion of the mails and agree to a subsidy of £500,000 per annum, half payable by the British Government and half by the Dominion Governments.

In view of the immense benefits that the successful establishment of such a service would confer upon the Empire and quite irrespective of its potential benefit to the Navy in case of war, it is not asking much from the Governments concerned, particularly when one bears in mind the subsidies which have been previously paid by different Governments for the establishment of mail services by steamers and advances at low rate of interest for the construction of special vessels, such as the "Mauretania" and "Lusitania." Personally I am pleased to think, from conversations with responsible members of the British Administration, that England will agree to such a contribution or subsidy as I suggest, for a term of years, provided that the Overseas Governments are prepared to share similarly and give their whole-hearted support to the service when established. I believe, too, that the British Government would be willing to make a cash contribution for a term of years in addition to the subsidy, provided they are thoroughly satisfied that the work to be done is a genuine attempt over a period of not less than two years and that the money will not be frittered away in desultory experiments without definite aim or policy.

In the meantime, we are all anxiously waiting to hear details of proposals placed before the Overseas Dominions by the Premiers of Australia, South Africa and New Zealand, and by the representatives of India. The Prime Minister of Australia is the first to come into the field and make good his promises and speeches at this end. Immediately on his return to Australia he arranged to place £500,000 on the estimates for the coming year for aerial matters. This, of course, includes provision for military aircraft in Australia, together with subsidies for the establishment of Interstate Aerial Services in various parts of the Australian Commonwealth. At the same time he has also proposed that Australia

should immediately set aside £250,000 to cover expenditure during the suggested two years for the experimental service recommended to the Conference of Premiers in London last July by the Imperial Air Communications Committee. Such prompt action is very gratifying to those of us who had the pleasure and opportunity of discussing air communications with Mr. Hughes during his recent visit to London. It now only remains for the Premiers of South Africa and New Zealand and the delegates for India to put forward similar schemes on behalf of their countries and then jointly request Great Britain to combine forces and the money can then be found to establish that Imperial Service which will make the biggest revolution in shortening time and distance between our several and separate entities, enabling Englishmen to know their Empire and Overseas representatives to sit in conference at frequent intervals with the senior partner of our Empire Company.

In my remarks I am assuming that the flights of the Zeppelins during the war, the voyage of the German L59 from Bulgaria to Central Africa and back, the historic flight of R34 to America and back, together with the desultory flying in England since the Armistice have, notwithstanding the loss of the R38, placed beyond all question of doubt the suitability of airships for commercial services over long distance routes. Before the introduction of the mooring mast the difficulties of shedding and unshedding such craft put them, in my opinion, completely out of commercial possibilities owing, first, to the large number of hands necessary to handle such vessels at every departure and arrival, secondly, to such departures and arrivals being entirely subject to weather conditions, thus reducing the number of days upon which sailings could be made and entirely preventing a definite schedule; and, thirdly, to the fact that notwithstanding precautions against flying upon unsuitable days every rigid airship destroyed prior to R38, and exclusive of damage through hostilities, was lost on the ground and not in the air. As an indication of the conversion from a non-commercial to a commercial proposition, the following figures of flights from Pulham demonstrate the difference made by the introduction of the mooring mast. From the 1st February to the 30th June, 1921, 164 flights were made from the

mooring mast, whereas at Howden, without a mooring mast and during the same period, it was only possible to get the ship out of the shed and fly on 30 occasions. The staff required to shed a ship even in light winds runs into about 350 hands; that to moor a ship at mast-head ten hands.

A considerable amount of money has been spent by the British Government in connection with meteorological matters, which necessarily play a very important part in aerial navigation both for aeroplanes and airships. The knowledge gained and the continuous reports from the various stations established, will be available for airships, and in the course of a few years air currents will be charted and as well known as surface winds. In his memorable flight to America in R34, Major Scott reports the great differences he found in currents and strength of wind between the surface and heights, say, of 2,000 feet and over. He found that in many cases of shallow depressions, an adverse wind of as much as 45 knots did not extend above 5,000 feet from the surface. It is more than likely, therefore, that the monsoons of the Indian Ocean do not attain any great height, and it is quite likely that when these winds are against the vessel a rise of a few hundred feet may place the ship in quite a different current and minimise the reducing effect of plugging into a dead head wind. In considering airship speeds the effect of the wind must be taken very fully into consideration. For instance, if a ship driven at 50 knots speed finds itself up against a wind of 40 knots the net progress is 10 knots only. Therefore, if the vessel had to cover, say, 100 miles and presuming the 40 knot head wind continued, it would take her 10 hours to cover that 100 miles, although she would have consumed fuel equivalent to flying 500 miles in calm weather. Therefore, under these conditions the ship has wasted 400 air miles. If, however, the vessel was capable of maintaining a speed of 60 knots in calm weather her progress would then be 20 knots per hour instead of 10 with the lesser power. Consequently she would only take five hours to cover the 100 miles, making her fuel usage equivalent to 300 miles, a wastage of 200 air miles instead of 400 air miles as first indicated. It is common knowledge to-day that the state of the weather on the surface does not give much indication of actual conditions at, say, 2,000 feet up and more. Once meteoro-

logical arrangements are complete and the required information available for communication to airships by wireless, it should be a criminal act for any captain of an airship to permit his ship to run into cyclones or other extreme wind velocities. In fact, it should be a regulation of future airship companies that any commander running his ship into such conditions should automatically be suspended or dismissed on arrival.

Since 1914 to the present date 134 rigid airships have been constructed, and it will be interesting to record their growth in size and the increase in proportion of disposable lift. The details are as follows :—

Type.	Gas capacity cubic feet.	Gross lift in tons.	Disposable lift in tons.	Percentage of disposable lift v. gross lift.
German				%
L3	794,600	24	8	33

R36	2,101,000	63	32	50
R38	2,724,000	82	50	61
				Built 14.

It is readily seen what a dominating position Germany has in this table, but for the moment she has no vessels, as under the Treaty of Versailles all airships in possession of that country at that date were destroyed by or distributed amongst the Allies. Exclusive of vessels destroyed through warfare, there is no record of any collapsing or crashing with loss of life until the great misfortune of R38. Admittedly many vessels were lost, but as I have said invariably on the ground and not in the air. In the air there is no doubt they are amongst the easiest vessels in existence to navigate and control, but on the ground they are unwieldy, and with any wind are apt to get out of hand, particularly when they are being shedded. This difficulty, however, has been practically overcome by the introduction by Great Britain of the mooring mast. The loss of R38 is of so poignant and recent occurrence that details of this

crash are unnecessary, but I would like to place on record my own personal appreciation of several of those gallant gentlemen particularly General Maitland, who lost their lives on that occasion. In my own mind there is no doubt as to the cause of this disaster. The court of inquiry set up by the Air Council reported on October 8th, 1921, "That on August 24th, 1921, at or about 5.38 p.m., the Airship R38, whilst flying at approximately 1,200 feet over the Humber in the neighbourhood of Hull, broke into two parts, due to failure of the structure in rear of the after-engine cars when being subjected to control tests." The court also drew attention

to the fact "that R38 was designed in August, 1918, in the Department of Airship Construction, Admiralty, to meet requirements which appear to the Court to be greatly in advance of those of previous British airships. That requirements as to maximum height and speed, together with the limits in length imposed by the only available construction sheds, necessitated the utmost economy in hull weights and materials. Many new features were introduced in the design, and it appears evident that in some cases there was a lack of vital aerodynamical information as to the effect of these modifications on the strength of the structure." There is no doubt, in my opinion, that the vessel in her control tests was asked to do considerably more than the calculated stresses of this experimental ship warranted. That some uneasiness was felt regarding the design of the vessel is evidenced by the

very terms and conditions of the contract between the British and American Governments for this ship. Without going into elaborate detail the transaction was arranged first by negotiations between the two Governments respectively to sell and purchase the ship in question. Owing to its experimental design the American Government asked for extensive tests to be conducted at the expense and risk of the British Government. This was refused, owing to the stiffness of the tests required by the Government of the United States of America, the final result being that the ship was completed on the understanding that she was purchased at an arranged price by the United States of America, subject to the satisfactory conclusion of tests to be carried out in the presence of officers of both Governments, and in the event of accident the cost to be equally divided between the two parties. The result is that the monetary loss occasioned by the loss of R 38 is equally borne by the British and American Governments. This seems to be fairly conclusive evidence that the design was largely experimental, and it is more than probable that if the vessel had been asked to undertake the normal trials to which these vessels had been previously subjected, the total loss would not have occurred. It has occurred, however, and there is no doubt whatever that every precaution will be taken to prevent a recurrence of such an appalling collapse. This personal opinion is also strengthened by a conversation I had with Mr. Campbell, the designer of the ship, who lost his life with the crew on August 24th. In connection with the proposals for an Imperial Airship Service that I was placing before the British and Dominion Governments, I visited the ships and sheds at Pulham and Cardington. When at Cardington the R38 was in shed undergoing some slight repairs necessitated by the previous flight. Mr. Campbell showed me the principal structural differences between that ship and R36 and the German Zeppelin L71. Subsequently, on thinking matters over, I felt uneasy on the subject of building commercial vessels on the lines of R38, and had a further interview with Mr. Campbell at my office in London. I expressed my doubt on this point and asked him whether in the event of an Imperial Service being established he would design on the lines of R38. Before I could express myself further, Mr. Campbell ex-

claimed, "Good God, man, no! R38 was specially designed in accordance with Admiralty instructions for purely war purposes to over-fly and out-fly all existing Zeppelins. We have, therefore, built her as light as possible to attain maximum heights, and she has very considerable engine power. When we build for commercial work maximum height and maximum speeds are not essential. With a war craft, if she serves her purpose during hostilities for, say, six months, she has achieved all that one would ask from her, but for commercial purposes you want strength and stability instead of lightness - and height. For commercial purposes we would simply elaborate R33 and R36." I then said, "Well, on a vessel of similar size to R38, what additional structural weight would you put into this size vessel for commercial purposes?" To this he replied:-- "Between 25 and 30 cwt. additional girder strength. With that strength and the knowledge and experience obtained through recent mooring tests we can build you a boat that will be absolutely safe, suitable for flying in any weather and one that will last for a good many years."

Bearing in mind therefore, the report of the court detailed above, together with the position as detailed in the conversation with the designer of R38 and myself, it is very essential that not only the Governments and the commercial interests, but the public at large, should realise the difference between vessels constructed for war and those constructed for peace. This might be further exemplified by realising that even in the Navy with the experience of 50 years behind us mistakes in design have been made. Do not overlook the fact that in Jane's "Fighting Ships" he records that the famous "Hush Hush" ships "Euriosis," "Courageous," etc., were all built to the same design at a cost of about £6,000,000 each. They were estimated and designed to steam between 40 and 43 knots per hour, but utterly failed on their steam trials to stand the water pressure on the bows, owing to the structural weakness through bad designing. The bows collapsed when the vessels were driven at full speed on trial trips. They were of course subsequently strengthened and no loss of life or accident occurred; but what I want you to realise is that here, after all our 50 years'

Naval experience, a fresh design failed to stand up to its calculated strengths, an identical position so far as I understand it to that of R 38. Even after strengthening these vessels they were unsuitable for their specific purposes and were converted into vessels to carry and launch aeroplanes, each vessel having a capacity to launch 10 planes. But at the prime cost of £6,000,000 each they were very costly vessels for such a purpose, more particularly in view of the fact that a vessel of the strength and design of R 36, costing then about £350,000, could carry and launch seven aeroplanes.

WAR SERVICES.—There is no doubt that the comparative failure of the Zeppelins in the War was a great disappointment to Germany and the knowledge of their present limitations as an offensive arm is no doubt the reason why our own military authorities have discarded airships from their list of armaments. It must be remembered, however, that owing to the mooring mast not having been invented, Zeppelins were only able to go on their bombing raids in fine weather. If Germany had had masts she would not have attempted raids on London in fine weather when visibility was good and every facility afforded to Great Britain for aeroplane flights and gun practice. With a mast the Germans could have flown on dull cloudy days and flying in the clouds could have been over London unperceived and practically undiscoverable, locating themselves by wireless direction from their bases in Germany. Under these circumstances it is doubtful whether we ever could have touched them. Their partial failure in the recent War should not be allowed to overshadow the great help they were to the German Fleet for scouting purposes and it may not be an exaggeration to say that the German Airship Service helped to save the German Fleet from annihilation at Jutland. There is no doubt whatever that they saved the German cruisers raiding our East Coast on more than one occasion. Admiral Lord Jellicoe, in his book, states that one airship was worth at least two cruisers, even with the limited number of days they were able to fly for the reason already stated. It seems to me, therefore, that so far as our Naval Defences are concerned we must not lose sight of the possibilities provided by airships for scouting and other purposes. At present we build fast cruisers

at a huge expense, but even the fastest cruisers can barely obtain 50 % of the speed obtainable by airships, while the latter's cruising height so extends their visibility as to place them for scouting purposes well ahead of any floating vessel yet designed or built. The procuring of Helium or some mechanical means such as air cushions that will prevent airships catching fire will add to their sphere of usefulness in time of war beyond all measure. When such a ship materialises, as it undoubtedly will, it will then be a very moot point whether the present superiority of an aeroplane for war purposes is not challenged. To-day, however, we are not concerned with this phase of airships, but the point must not be overlooked. There is no doubt that continued use for commercial purposes will develop many improvements which will be of immense use in commerce or war, particularly now that the scene of action is changed from the North Sea to the Pacific Ocean. In the North Sea our Fleet was under our eyes and within immediate touch, but in the Pacific Ocean or some other far flung portion of the globe, it will be by the air alone that we shall be able to get in personal touch with our Commanders. Airships with their extended scope of action are immeasurably superior to aeroplanes for this class of work. They also have many other uses, a few of which I will briefly refer to :—

(a) It may be of great value to a Commander-in-Chief to know that no hostile fleet has passed a certain channel, e.g., the Great Belt or the Straits of Gibraltar. If a passage is unwatched for even a few hours a hostile fleet may be through, and the Commander-in-Chief must take that into his calculations. No craft is so suitable for watching work as airships, as they can stay for days on one position observing a much larger area of water than surface scouts and immune from the risk of submarine and mine. They are also cheaper than surface craft, as is easily seen when you realise that a modern airship can keep about 100,000 square miles under observation per 24 hours and that it would take at least six surface craft to observe the same area and even then not as efficiently. Again, if lost for any reason only about one-tenth of the number of officers and men are lost compared to the total loss of a light cruiser.

If filled with non-flammable gas, or gas

armoured, she can only be destroyed by a hit from a big gun or a large charge exploded in close proximity.

(b) *Anti-Submarine Work.* The use of airships for this work may be taken as proved. For many months no convoy escorted by airships was attacked. The only fault they possess is that they are slow in getting at a submarine sighted up wind. To meet this case at the end of the war, airships on coastal convoy work were being fitted to carry a fast aeroplane which could be slipped to attack immediately on sighting the enemy. For submarine hunting by using hydrophones the airship is specially suitable as there are no water noises from the hull, such as exist with surface craft, to interfere with listening. Again, to assist submarines an airship can be taken in tow and keep in telephonic communication with the submarine under water.

(c) *Mine Clearing.* Some mines are exploded by the noise of a ship's propeller, some by bringing a mass of metal over them. These are difficult and dangerous to clear by surface craft, but an airship can tow an instrument over them designed to imitate the beat of propeller, etc., and so explode the mine. Airships were used to assist trawlers to find and buoy mine fields and to follow our own mine layers to see that the mines took their depth properly.

(d) *Bomb Dropping.* The use of the ordinary bomb dropped vertically is well-known. The U.S.A. Army Air Service have proved that one ton of high explosive will destroy a battleship if dropped close alongside and exploded under water. The next development will be the Wireless Controlled Gliding Bomb. Gliders up to half a ton have already been dropped from airships. Captain C. Ryan, R.N., has made a motor launch (500 h.p.) which has been stopped, started and steered very successfully by wireless from the air. It is only necessary to put the essential gear in a glider carrying a ton of explosive, slip it and steer it by wireless till it hits a ship and falls into the water alongside, exploding there. From a height of 10,000 feet it should be possible to hit a ship 30,000 yards away, i.e., out of gunfire. For longer ranges it will eventually be possible to use an unmanned aeroplane instead of a glider, the weight of engine correspondingly reducing the explosive carried.

I look on this as a most important possibility. It definitely threatens the existence

of the capital ship and can only be met by aerial defence of some sort. Therefore, some portion of our Navy must fly.

(e) *Transport Work.* Cheap non-rigid or semi-rigid airships not necessarily requiring masts can now be built to carry loads of seven tons slung from a single point for about 200 miles at 50 m.p.h. This weight means 70 men, or guns, or stores, etc. In a country with bad communications it would be invaluable to the Army to take up stores and provisions and bring back sick and wounded. They could also be used for transporting aeroplanes for military work. The R.A.F. prefer to pack their aeroplanes in crates even for despatch to Ireland. It takes about three months to test an aeroplane in this country, un-rig, pack and despatch by sea to Egypt, re-rig and fly it. An airship of to-day could take 10 aeroplanes to Egypt, rigged ready for flight in three days. Further, with a mother ship fitted with mooring mast and apparatus for making gas, airships could go to any storm centre in any part of the world and patrol disturbed districts.

The establishment of such an Imperial Route would therefore be of great value, both in time of peace and war. During peace the cost of installing and maintaining such a chain of stations for war purposes alone, practically places it beyond the bounds of possibility, but such a chain established for commercial usage would undoubtedly be availed of by military machines in the various vicinities, whilst in case of war the whole fleet, personnel and plant would immediately be available as a going concern. During the peace period, too, facilities could be afforded to train members of the Naval Service.

With the reduction of our Navy which followed the Armistice, the further reduction proposed by the Washington Conference and with the knowledge of all the above possibilities, is it conceivable that the Naval Authorities would have agreed to transfer Naval Airships to the Air Ministry, if they had known that within a short period the Ministry would discontinue airship services and concentrate upon aeroplanes?

In considering estimates detailed in the appendix it should be borne in mind that the probabilities are that the items on the expenditure side are maximum rates and that experience in commercial flying will enable considerable reductions in several items to be made. For instance:—

(a) At present when coming down a percentage of gas is lost through valving. Experiments were being made to use such gas for power purposes and there is every reason to believe that the experiment discontinued when the Government closed down would have made practical this proposition. The satisfactory solution of this difficulty means a double saving, inasmuch as instead of wasting the hydrogen it is utilised for power production and its utilisation lessens the consumption of petrol, reducing the quantity to be carried as a reserve, thus adding to the commercial lift.

(b) So far, airship engines are identical with or converted aeroplane engines. There is no doubt but that the commercial adoption of airships will lead to the production of engines specially designed for this class of work and there seems no reason why the evolution of engine practice in connection with submarines should not be repeated here. The early submarines were petrol driven. Then kerosene came along and finally the last submarines were using crude oils. It is almost certain that the same results will be achieved in airship engines. Such an evolution has a two-fold effect, inasmuch as running costs and the risk of fire both decrease as such changes become effective. Kerosene is not nearly so inflammable or as costly as petrol and crude oil is still cheaper and practically non-flammable.

(c) Another line of research to cheapen power is the admixture of hydrogen with all three fuels mentioned, viz., petrol, kerosene and crude oil. Experiments so far indicate that the burning of hydrogen with these three fuels adds considerably to efficiency and consequently reduces expenditure.

(d) The cost of hydrogen gas in the estimates referred to is taken at 10s. per 1,000 cubic feet, but British manufacturers of gas plants state that they are prepared to contract to erect plants to produce hydrogen gas at 6s. per 1,000 cubic feet, with a possibility of an even lower cost.

(e) Overhead expenses at air ports or bases can be considerably reduced. At present the entire cost of maintenance is included in the estimated expenditure, but it is fairly obvious that these bases, which for some years, at any rate, would not be fully utilised by the airship services, could be utilised for private work. These bases

must of necessity have well fitted ships and it should not be a difficult task to secure sufficient work from the vicinity to keep them well employed, thus effecting a considerable reduction in this portion of the total running cost of a ship. Then as the number of airships increases overhead expenses automatically decrease proportionately.

In addition to the possible running cost reductions already mentioned, it is probable that considerable improvements in hull construction will take place, and reference to a few of these matters will be of interest to those considering the scheme in its Imperial character. They are as follows:—

(1.) FUEL CONTAINERS. There is no doubt that the breaking of the girders of R38 caused some of the petrol containers to crack or break, with the result that the contents leaking out and mingling with the air were fired either from the exhausts of the running engines or by current from the broken electric leads, and whilst it is unlikely that any future vessel will be constructed that will permit of a similar collapse to that of R38, it may still be desirable, whilst petrol continues to be used, to construct such containers as will minimise this risk. I understand that experiments on these lines are now proceeding in connection with containers for aeroplanes, so it is more than probable that we shall see a solution of this difficulty at an early date. Personally, however, I look to the adoption of the Diesel engine as already mentioned to overcome this risk.

(2) HULL FRAMING. The earlier Zeppelins were constructed of aluminium. Their rivals, the Schutte Lanz Company, built their vessels of wood as giving superior results to aluminium. The Zeppelin people then came along with an aluminium alloy called Duralumin, and all their recent vessels, as well as those constructed in Great Britain, were built of Duralumin channels. At the close of the war the Schutte Lanz Company had under construction two vessels with framing of Duralumin tubing, these being the first vessels constructed with tubular frames. Unfortunately, they were never completed, as upon the signing of the Armistice they were destroyed by the builders to prevent the information and knowledge of this form of construction falling into the hands of the British. It is considered that a vessel with tubular

framing will, with the same strength, be lighter than a similar vessel built with channel framing. In England we were experimenting with another aluminium alloy, and to-day are actually producing a metal which bulk for bulk is cheaper, stronger and lighter than the Duralumin of Germany.

(3) GAS HOLDERS. The present containers, with their lining of goldbeaters' skin, are very expensive, whilst the supply of the latter is not unlimited. Just prior to the Armistice the British authorities had decided to construct experimental bags with a new synthetic liner instead of the goldbeaters' skin. Unfortunately, upon the declaration of the Armistice the instructions were cancelled, and the experimental bags never completed, but discussing this matter at Cardington on one of my visits, I was assured that the preliminary tests had fully satisfied our technical staffs that they could produce a bag more satisfactory, cheaper and with a longer life than bags lined with goldbeaters' skin.

(4.) ENGINE UNITS. With all commercial airships the different gondolas containing the engines will be detachable and transferable, so that in the event of any separate engine developing trouble during the voyage the gondola with the engine would be detached at the first station holding a reserve unit and there replaced. Then at a general overhaul such a provision will enable a vessel to be re-engined entirely in a few hours, thus reducing the loss of the ship's running time.

In the report of the Imperial Air Communications Committee to the Premiers' Conference, they detail estimates of capital required and working costs to run separate fortnightly services to South Africa, India and Australasia, basing their calculations mainly upon war costs and the period immediately following the Armistice. These figures are the absolute maximum, and in view of the big reductions that have taken place and the further reductions that will take place are consequently misleading. They give the cost of 12 new airships as commencing at £300,000 reducing to £240,000, an average cost of £247,500 each. During the war the Zeppelin Company built their ships at the cost of about £150,000, and since the Armistice have quoted America ships similar to those suggested for the Dominions service at £175,000. There is no doubt that with a block order for anything like 12 ships, upon which the

Committee's estimate is based, British firms would be prepared to supply at about £150,000 each. In the calculations detailed in the Appendix the cost of the ships suggested for the permanent Colonial Service is taken at £200 000 each, a figure which I feel sure will provide a margin on actual cost if we are able to place orders for not less than six ships in one contract. Similarly with masts and all ground plant, including sheds. They estimate the cost of new two-berth sheds at £250,000. A very large and well-known firm are to-day prepared to erect a duplicate for about £130,000, and would supply all the steel and erect in England a complete mast ready for use, but exclusive of lift, winches and wire rope for £2,700. The Committee also state that a total capital expenditure of £4,500,000 is required, and whilst it is quite possible that that amount may eventually be wanted, it is not an immediate demand and would not be required if the testing out of the experimental service proved a ghastly failure. It is only the successful initiation of the business that will necessitate the large capital expenditure. Consequently, a considerable portion of the amount stated by the Imperial Communications Committee as required for capital expenditure would only be wanted after the proposal was a proved success. I gather, too, that their estimate for such services is based upon a flying capacity of 2,500 flying hours per ship per annum. In consultation with responsible officers of the Airship Service I learn that with new airships specially built for the service they would probably fly approximately 5,000 hours per ship per annum. I feel sure that the estimate of 2,500 flying hours per ship upon which the Imperial Air Communications Committee base their estimates is altogether too short, and whilst it might be unsafe to calculate upon the estimate of 5,000 flying hours per ship per annum, it should be a very reasonable and conservative estimate to base costs on 3,500 flying hours per ship per annum. It is on this basis that my figures are calculated. Again, presuming that communication with Australasia is first opened up via India, it will certainly not be necessary to provide separate services for Australasia and India, although in the course of time it is probable this would be so. To maintain a fortnightly service to South Africa via Egypt would require two modern airships and a

fortnightly service to Australasia via India would need four modern airships, with an additional ship in reserve. Arrangements would be made to alternate the different ships between the two routes so as to give each vessel as near as possible the same amount of actual mileage. With this understanding it is believed that seven airships would be sufficient to maintain a fortnightly service on the routes indicated. In three or four years time, when the traffic justified additional boats, they could then be easily provided, but in the meantime to include capital for this provision is unnecessary and simply swamps the proposal in its immediate aspect. The safest way to inaugurate the service would be to establish the ground plant to maintain a fortnightly service commencing first of all with the existing airships purely as experimental vessels for such distances as they can be conveniently and commercially utilised. As soon as their limitations are definitely ascertained seven new boats could be ordered with confidence. These could carry on for probably three or four years before further capital expenditure on new vessels would be required.

Owing to the limitations and restrictions imposed upon Germany, that country to-day is not the great and active competitor for the world's routes that she will be when these restrictions are removed. To-day the German personnel are chafing and straining at the leash, anxiously waiting for the moment that they will be free to tackle the world's aerial routes. As a matter of fact, it is questionable whether even with these restrictions Germany is not attempting to hold her position in this matter. A company has just been registered in Spain with an authorised capital of 100,000,000 pesetas, say £3,750,000, to establish flights between Spain and Buenos Aires. Two of the Zeppelin directors are on the board of the new company, and ships are to be constructed on the plans of the well-known Zeppelins. The Spanish and Argentine Governments have agreed to refund the company the cost of the sheds and ground plant at the two termini, such payments being spread over a term of years. The Argentine Government has offered a subsidy of 2,000,000 pesetas (about £70,000) per annum for mails, but it is understood that this amount will be increased, whilst the Spanish Government have also agreed to subsidise, but the amount has not yet been

fixed. Germany is also flirting violently with America in connection with the latter's determination to establish their own airship service between the Atlantic and the Pacific. The American preliminary company is at present limited to 30 members, each individual of which is in the front rank of huge American interests, either Government, industrial, banking or oil. I understand they have obtained certain options from both the Zeppelin and Schütte Lanz Companies to permit airship developments within the United States, and that it is more than likely that with the permission of the Allies one of these German companies will construct a large and modern vessel for use within the confines of the United States. Meantime, the United States Government have already erected the largest airship shed in the world at Lakehurst, New Jersey. This shed is capable of accommodating one vessel of 10,000,000 cubic feet capacity or two each of 5,000,000 cubic feet capacity. Sheds are also being erected at Cape May and Langley Field somewhat larger than any at present existing in England and capable of housing ships up to 4,000,000 cubic feet capacity. I understand, too, that the Government of the United States of America are at the present moment also engaged upon the construction of a rigid ship on the lines of the German Zeppelin L49. Once the preliminary company have decided upon a definite policy there will be no lack of money or Government assistance behind the concern to push the business to its maximum lengths.

It has been the experience of the world that all new means of communication or conveyance invariably first pass through a period of scepticism, ridicule and doubt, so much so, that the early stages of any important development have been invariably conducted at a pecuniary loss. It is the realisation of this basic fact that makes the commercial world chary of shouldering the burden for development of airship communications. Owing to the huge amount of money that has to be sunk, not so much on the actual ships themselves, but in the sheds, mooring masts, gas plants and ground equipment, in the different places to be touched at, together with the fact that this extensive organisation will only be utilised in the early stages by a very small number of ships, thereby casting an undue percentage of overhead costs upon the number of running trips conducted, Govern-

ment assistance will be essential for some years to come in order to establish this new method of communication, but I will deal with the Government contributions in another paragraph.

In the meantime, I simply desire to record the wonderful and tremendous opportunities that the successful establishment of such a means of communication will provide, and it must be borne in mind that no nation occupies the same favourable position as the British Empire for the establishment of an aerial service. Further, it is a fundamental necessity that quicker communications between the component parts of the Empire be established. Our Dominions are so placed that we need touch no foreign soil in establishing and maintaining our Airship Service, but, of course, there is no reason why we should not do so, and thus add the trading with foreign countries that will undoubtedly develop along our main routes.

Our first step must be Egypt, the country that eventually will be the Clapham Junction of our aerial services. Between London and Cairo it would be practicable to call at Marseilles and Athens, and there is no doubt the Governments of both France and Greece would be pleased to provide facilities for the call of British airships. These facilities would, in turn, provide the nucleus for subsidiary services from their immediate neighbourhoods, and such intermediary services would, in most cases, be supplied by aeroplanes. After arrival at Egypt, two extensions naturally follow, one to South Africa via Mombasa, and the other to Karachi or Bombay via Basra. The extension to Australia and New Zealand could follow from either of these termini (Karachi or South Africa), later developments determining the more suitable route. If from South Africa to Perth or Fremantle the vessel would invariably be helped by the recognised trade wind of this locality, but it is a big distance, and even with the help of the wind, entails a reduction in the commercial carrying capacity, owing to the extra quantity of fuel that would be required. At the same time, many airmen seem at present to favour this route because of its favourable winds, but it may be that, owing to commercial necessities, shorter termini distances may more than set off the favourable trade wind mentioned. Personally, I am in favour of the alternative route to Australia from Karachi via Colombo,

Singapore and Java. From Java, the first Australian call would be in the vicinity of Perth. From that point either service would then follow on to Adelaide, Melbourne, Sydney and Wellington, returning by the same route. If, on the outward voyage from Egypt the Cape Town route was selected for Australia, it would be difficult to return this way, and it is more than likely that the Indian route would be selected for the return journey. Again, there is practically no trade from Africa to Australia, whereas there is trade between India and Australia, so that it would be quite possible on the Indian route to carry intermediate passengers and cargoes at proportionately higher rates, an undoubted attraction from the commercial point of view.

With a map of the world before you, and picking out the different points I have indicated, what a wonderful vista of commercial possibilities confronts us. The main routes would, in a very few years, be tapped at every point of call with subsidiary aeroplane and airship services. As to the personal advantages which such communications would give, they are almost without number. To-day, if we leave Tilbury for Melbourne by the fast P. & O. or Orient mail boats, it takes up 39 days from port to port. If, however, we travel overland and join the vessel at Marseilles or Toulon at this end of the voyage, and disembark at Fremantle, travelling by rail to Melbourne, we can reduce this to 34 days, but with an airship service, we could easily reduce it to ten days, even after allowing time for the vessels to moor and passengers to land for two or three hours at, say, half a dozen ports en route. Passengers would be entirely free from that present bugbear to so many of us against travelling, viz., sea sickness. The motion in an airship is entirely different from that in an aeroplane or steamer, there being, in fact, practically no motion whatever, and once you have overcome, as you do in a very short time, the feeling of vertigo when looking down, there is absolutely no sensation whatever. In the passenger car of the future aerial liner, one will sit at comfort without noise, vibration or motion, no dust or dirt as in a railway train, converse, write or play cards with perfect freedom, and from time to time, stretch one's legs from one end of the boat to the other. On the other hand

in aeroplanes, ordinary conversation and freedom of motion are impossible; consequently, on the question of the mental and personal comfort of a passenger, I doubt whether, with the present type of aeroplanes for long distance routes, it would be possible to average more than from eight to 10 hours flying per day. Whilst, therefore, the actual rate of flight in the air would be greater than airships, over a journey of a considerable length, it is more than likely that the airship would deliver the passenger in the shorter time. There is no difficulty, either, in the maintenance of an equitable temperature, so that we need not suffer the vicissitudes of extreme heat or extreme cold.

Then, can any one foresee the results of bringing Australia and New Zealand to within, say, -10 to 12 days of London? It makes possible, not only political conferences upon matters of vital importance to all portions of the Empire, but the commercial developments which closer association will undoubtedly bring in its train. Speak to-day to a big London business man or manufacturer, about possibilities in Australia, which could only be judged by his personal inspection. He looks at the time table and sees that even under the most favoured conditions, and only allowing a fortnight in Australia, it would take him about 82 days to accomplish the trip. With the establishment of airships he could make the same journey in 34 days. With such facilities there is no doubt but that there will be a very big expansion of British interests in all the Overseas Dominions. For a service of this description, too, mails are a necessity, and a working agreement between the Governments concerned would be essential so that the Airship Service could receive a sufficient and regular quota of mails for each vessel. The quick delivery of urgent goods would also stimulate trade between the far distant portions of the Empire. For instance, to bring in an individual note. What lady in Australia or New Zealand would mind spending, say, 30s. to 40s. in freight on a dress of the latest London model, instead of, as at present, being three to four months behind London fashions? Finally, the transfer of bullion and bankers' securities would mean a tremendous saving in interest, but none of these alluring possibilities can be brought into existence without the assistance and

co-operation of the Governments concerned.

The whole position of airships boils itself down to one fact. At the present moment airships are practically controlled by military authorities, who have decided that as an offensive arm they are inferior to aeroplanes. Consequently, the sooner we get rid of airships the better this section of our military forces will be pleased. Such a view, however, entirely overlooks the Imperial character of an airship service, its immense benefit to the Navy, and its tremendous commercial possibilities. At the present moment, the military view of airships seems to be dominant, but it is inconceivable to me that the Imperial, Naval and commercial interests of this great country will permit a purely military opinion to sacrifice the possibilities which to so many of us are crying aloud for consideration and reasonable support. It may, perhaps, require a strong demand from the Overseas Dominions thoroughly to awaken Britishers to the danger which undoubtedly exists if the break up of plant and personnel is persisted in. That India, Australia, South Africa and New Zealand are fully alive to the potentialities of airships is, I think, clear, notwithstanding the fact that so few of the residents Overseas have had the personal opportunity of sighting or voyaging in existing airships. Mr. Hughes, the Prime Minister of Australia, has clearly indicated his belief and strong conviction, and his prompt action on his return to Australia is only what was to be expected from a man of his vision. Similar action by Africa, New Zealand and India will doubtless follow, but it should not take the combined demand of all these entities to overcome the lethargy undoubtedly existing in certain British Government circles regarding the undreamed of developments that will ensue from the successful initiation of a combined Imperial Service. The solution of the problem is for the Dominions to put up a definite proposition to Great Britain and ask the latter to join with them in helping ourselves to help each other.

APPENDIX.

The estimates are based on figures given by Lieut.-Colonel V. C. Richmond, in a paper read by him on October 17th, 1921, before the Royal Aeronautical Society, Scottish Branch. My calculations are, however, based in addition thereto on fortnightly services to

South Africa via Egypt and to Australasia via Egypt and India, utilising seven airships for such services, with reserves.

CAPITAL EXPENDITURE.

	£
Four new airships at £200,000 each	800,000
Refitting R36 and L71, say ..	50,000
Complete R37	25,000
Alterations at Cardington ..	30,000
Cairo Base—Removal and erection of existing air sheds with gas plant, mast, etc. ..	285,000
New Bases—Melbourne and South Africa, each £400,000	800,000
Mooring Mast Stations with masts and gas plants, etc.—9 at £47,600	428,400
Exclusive of Land and Working Capital—Total.. .. .	£2,418,400

ANNUAL EXPENDITURE.

Base.	Cardington	Egypt.
	£	£
Maintenance of base ..	10,000	10,000
Electric light and power	3,000	3,000
Advertising and Office expenses	10,000	6,000
Personnel—wages and salaries	55,000	40,000
Transport	1,500	1,500
	£79,500	£60,500
Base.	South Africa.	Melbourne
Maintenance of base ..	10,000	10,000
Electric light and power	3,000	3,000
Advertising and Office Expenses	6,000	6,000
Personnel—wages and salaries	40,000	40,000
Transport	1,500	1,500
	£60,500	£60,500
Total		£261,000

Per Station
£

Mooring Masts—

Maintenance	1,000
Electric light and power	1,500
Advertising and Office expenses	1,000

	£
Personnel — Wages and salaries	7,000
Transport	1,000

Nine Stations each £11,500 = £103,500

Ships.

Salaries of 7 crews (1 in reserve) each	£12,000	84,000
Petrol—2,500,000 gallons at 2/6		312,500
Hydrogen—300,000,000 cu. ft. at 10/- per 1,000 cu. ft.		150,000
Food for crew and passengers at 7/- per head per day		26,000
Material only for maintenance, labour being already included in the base personnel ..		80,000
Administration, including London Office ..		40,000
Depreciation—Buildings and Plant, say ..		55,000
7 airships, 20 per cent.		280,000
Insurance — Buildings, plant, etc., £2,200,000 at 10/- per cent. ..		11,000
Airships — £1,400,000 at 10/- per cent., the company probably acting as their own underwriters ..		140,000
		1,178,500

Sundries and contingencies

say	100,000
	1,278,500

Total £1,643,000

REVENUE.

It is, of course, quite impossible to give reliable estimates of the revenue that will be actually received. One can only tabulate the sources of revenue and leave each individual to form his own idea of the proportion of each item likely to be secured both immediately and as the service successfully develops. The following schedule gives the yearly traffic in the selected items between Great Britain and South Africa, and India and Australasia.

	Passengers in and out	Rate of Steamer Fare £	1st Class Mail Matter Tons.	Present rate of Postage. 1½d. each ounce	Parcel Post in and out tons.	Parcel Post Present Rates.
South Africa	15,329	97	355	2d. for first ounce, 1½d. each additional ounce	322	9d. per lb. up to 3lb., 1/9; 7lbs. 3/6; 11lbs. 4/9
India	26,223	90	485	ditto	573	ditto
Australasia	7,998	175	312	ditto	364	1/4 for first lb., 6d each additional lb.

Special Freights.

Articles.	Value.
South Africa. Diamonds, Furs, Feathers, Chemical Preparations, Drugs and Scientific In- struments.	£7,980,603
India. Furs, Chemical Prepara- tions, Drugs and Scientific Instruments.	£1,586,601
Australasia. Furs, Chemical Prepara- tions, Drugs and Scientific Instruments.	£1,615,434

GOLD.

In addition to the above there is also the transfer of gold from Africa and Australia to Great Britain and the re-transfer from Great Britain to India. Actual figures of gold transfers are difficult to secure, but it is estimated that bullion to the extent of £80,000,000 is annually transferred between these three centres each year. At present, it takes an average of 21 days between South Africa and England, 21 days between England and India and 42 days between England and Australia. There is no doubt that an average saving of at least 14 days would be achieved by airship transfer, so the saving in interest alone on £80,000,000 for 14 days at 5% amounts approximately to £153,425. Similarly bankers' negotiable documents could also be transferred with the same saving of time and consequent saving of interest. Assuming, therefore, that a fortnightly service with airships capable of providing lifting

capacity of 20 tons for commercial purposes (passengers and freight) and calculating that each fortnightly trip on each service only averaged two-thirds of its commercial lifting capacity it would give the following result :—

Colony. 52 Trips per year,
calculating 14 tons
earning capacity, in-
stead of the actual 20
tons available.

South Africa.

40 Passengers and baggage=	
6½ tons=2,080 Passengers	
at £100 each.	£208,000
Mail matter—2 tons=104	
tons at 9d. per oz.	£139,776
Special Freight 6 tons, say	
300 tons at 10/- lb.	£336,000

India and Australasia.

50 Passengers and baggage=	
8½ tons = 2,600 passengers	
at £100 per head for India	
and £200 for Australasia.	
Proportionate for inter- mediate.	£520,000
Mail Matter — 4 tons — 208	
tons at 9d. per oz. for India	
and 1/- oz. for Australia,	
calculated at 1/- per oz.	£372,736
Special Freight — 2 tons =	
104 tons at 12/- per lb.	£139,776

The total Revenue may, therefore, be summarised as follows :—

Passengers ..	£728,000
Mail Matter ..	512,512
Special Cargo ..	475,776
	<hr/>
	£1,716,288

Subsidy required from Great Britain ..	250,000
Subsidy required from Overseas Dominions	250,000
Estimated Revenue	£2,216,288

DISCUSSION.

MR. M. L. SHEPHERD (Acting High Commissioner for Australia) in opening the discussion, thoroughly endorsed Mr. Ashbolt's remarks with regard to the efforts of Mr. Hughes, and assured the audience that Australia was intensely interested in any scheme of the kind which would bring her closer to the heart of the Empire. The present condition of affairs, in which Australia was between 30 and 40 days away by mail, was one which the Commonwealth looked upon with very great dissatisfaction. As an instance of Australia's bonafides, Mr. Shepherd mentioned that Mr. Hughes, immediately on his return to Australia, put the matter before Parliament, and it had been referred to again during the last few days, when Mr. Hughes again confirmed his intention of going on with the scheme if the British Government was prepared to do so. Mail services with flying machines had already been started between certain points in Australia, and many more were under consideration. Meanwhile, the preparation of landing grounds and the necessary accommodation for flying-machine services between various capitals in Australia was being rapidly proceeded with. It would be seen, therefore, that Australia was intensely interested, and in earnest in regard to aviation.

CAPTAIN SIR ROSS MACPHERSON SMITH, K.B.E., M.C., D.F.C., A.F.C., remarked that he had not had practical experience of airships himself, but he had watched their progress for some time, and had also talked with various experts of the airship branch of the Service; and the conclusion he had come to was that the airship of the present time was a perfectly sound means of transport. The present was an age of rapid transport, and anything which could carry from one place to another more quickly than at present was a great boon for the whole community. He had often been asked his opinion of an aeroplane service between Great Britain and Australia. He had always maintained that an aeroplane, if looked after properly and treated in the way it should be treated, would fly anywhere; but he understood that the machines flying between England and Paris at the present time had an economic range of 500 to 600 miles, which meant that if those machines started to fly to Australia the flight would have to be done in relays of between

500 and 600 miles, and with relays of aeroplanes. That would mean that a passenger would have to land every five or six hours, which would be a big strain. He thought the solution of the whole difficulty was to use airships for long-distance work and to use aeroplanes to feed them, the latter concentrating on the points at which the airships landed, thus having the two services working together. He sincerely trusted that Mr. Ashbolt's scheme would have the success and the support which it so richly deserved.

LIEUT.-COLONEL V. C. RICHMOND (Air Ministry) thought all were agreed that Mr. Ashbolt, in his paper, and also in his various other activities to promote an airship service to the Dominions and India, had done pioneer work for which he deserved the utmost appreciation and thanks. There could be no doubt whatever that the British Empire was the soundest and most profitable ground for the development of enterprises of air transport, being unique, as it was, in possessing routes over which there was everything to gain by such means of transport. The necessity, both political and economic, for bringing the Colonies into closer touch with the motherland had been emphasised at the recent meeting of the Dominion Premiers in London; and seeing how great was the necessity of such communication, it was quite natural for thinking men to ask themselves how that was to be brought about. To build a steamship which would have a speed of anything approaching 50 miles an hour was almost a technical impossibility, and the cost of building a fast steamship was so enormous as to require a subsidy out of all proportion to that which airships would want to do the same service. The question, therefore, seemed to be whether an airship service was technically possible, and if so, whether it could be made self-supporting at the start, or, if not, whether it was worth subsidising. The recent Committee had not questioned in any way the practicability of airships from a technical point of view. Within a short time enormous strides had been made, and most revolutionary developments were in sight. These were most unfortunately held up for the present, but as soon as there was an incentive to go on, he felt sure that those developments would be brought to fruition. It was obvious that an Imperial airship service could not pay its way at the outset; there would be the big capital cost of the bases and the educating of the public to the immense advantages of that means of transport. As far as the final benefit of the service was concerned, speaking as a technical man, he might say that if the airship could fly to India at all it would reach India in five days. There was no need to enlarge on this statement. The audience could be safely left to judge the immense benefits which

would be gained from this single item alone. The urgent need for quicker communication must be met. His Majesty the King, in his address to the Dominion Premiers when they left the country, issued a call to the men of science to find some means of producing more rapid communication with the Colonies. He (Col. Richmond) would humbly suggest that one of the many benefits derived from the terrible scourge of the late war was that men of science had already produced such an instrument in the airship which was capable of carrying out His Majesty's hopes and wishes.

MAJOR-GENERAL SIR WILLIAM S. BRANCKER, K.C.B., A.F.C., congratulated aviation on having obtained, from outside itself for a change, such an able champion as Mr Ashbolt. As a rule, most people connected with aviation were looked upon merely as amiable enthusiasts not to be listened to very seriously. Mr. Holt Thomas, who was at the International Air Conference in Paris, had asked him to place before the meeting his views on the question of the airship. Mr. Holt Thomas firmly believed in airships for commerce, and that speed was the greatest boon which aviation was going to give to commerce. He was rather averse from plunging at once into a definite airship service round the world until further data had been obtained, and he was under the impression that the present 60-miles-an-hour airship was not fast enough for the long routes which Mr. Ashbolt had mentioned, unless, after meteorological reconnaissance, it was found that in going backwards and forwards to Australia winds were available to help both ways by following definite routes. Personally he (Sir William Brancker) thought it was quite possible that the best route to Australia would be via Africa, and that the best route back from Australia would be via South America. Mr. Holt Thomas felt that the Government should certainly go on with airships, that, even in their present condition, they were a very efficient Naval weapon for reconnaissance, and that experiments on long air routes should certainly be continued. He considered that the mooring mast was the greatest development in commercial air work that had been brought about in recent times.

Turning to his own views, Sir William Brancker said he was usually called an aeroplane man, and was supposed to be biased on the side of aeroplanes; but, actually, he was not. He was very keen indeed on airships and their development. He considered that it was an absolute scandal that the Government should have ceased to continue experimenting with them, and to have reduced the development of airships to its present really futile and hopeless condition. "A non-inflammable gas would turn an airship into a dangerous military weapon

to-morrow, and a little more development in the size and speed would make it a great commercial asset. He went further than Mr Holt Thomas, who said that the only boon that aviation would give to commerce was speed. The airship would give also comfort. He would far sooner travel by airship than by steamer. Taking Mr. Ashbolt's figures, the airship would give economy. Those figures, moreover, made him think that a subsidy was hardly necessary. Mr. Ashbolt quoted a fare of £100 to India or South Africa. He thought quite a sufficient number of passengers would be found who would be willing to pay £200, and in that case that would leave very little to be supplied in the way of subsidy. The Government attitude towards aerial transport was, "What is the good of it unless it is going to pay?" He said it could pay, and would pay to-morrow if the Government would give a guarantee of a really large load of mails. But even if an airship service was not going to pay, why should it be of no use? The telephone service did not pay, but nobody would like to be without it. The railway and telegraphic services in Central Africa or in the undeveloped parts of India had not paid at once. It was not proposed to stop all railway and wireless and telephonic development because those services did not pay in the first instance. But aviation could and would pay if it was properly assisted and run. He thought it was time for one of the leading shipping companies to work out a plan for the future running of their ships at 12 or 14 knots; instead of the present high speed, and of running in conjunction with those slower-speed ships an airship service at 60 miles an hour. They could carry the mails, and the rich passengers could afford to pay for speed, in the airships, and the ordinary passengers could plod along at 14 knots at considerably lower rates than they were paying at present. The cost of shipping to-day was largely due to the high speed demanded, and if the shipping companies were prepared to cut that high speed for the ordinary average individual and put the savings into an airship service, a more practical and economical situation would result. Mr. Ashbolt had said that the Air Ministry was necessarily dominated almost entirely by military influence. Why "necessarily?" When Lord Weir left the Air Ministry he left a great heritage. He had been a firm believer in aerial transport, and there would have been no military influence if he had continued there. Aerial transport had been severely and definitely let down by the Government policy of 1919-20, and now, even with the best of intentions, it was very hard indeed for the Air Ministry to recover that lost ground, firstly, because the financial situation was extremely bad, and, secondly because the name of aviation had been blackened in the eyes of the Treasury, who would not now be persuaded into spending money on it. 118

believed absolutely in the airship. The aeroplane and the airship could work perfectly amicably side by side. They were not rivals; they were firm allies. This wonderful Empire of ours was spread out all over the world. Its one cry was for closer communication, and aviation was the one thing that could give it that, and if we did not get it, either we or our children would repent most bitterly. Therefore it was up to the British public to continue agitating until the Government did apply foresight and common sense and proper economy to the development of both the aeroplane and the airship.

CONSTRUCTOR COMMANDER H. B. WYN EVANS, M.B.E., M.I.N.A. (Royal Corps of Naval Constructors), said that as one who had been intimately connected with the design and construction of rigid airships since 1915, and who had taken part in a considerable number of flights in most types of aircraft, and hence realised their respective limitations, he felt sure he should be excused for wishing to make a few remarks. Mr. Ashbolt was to be congratulated on his great paper. He deserved the thanks, not only of those who believed in airships, but of all British peoples. He had first met Mr. Ashbolt when he visited the Royal Airship Works at Cardington a short time ago, and travelled back to London in his company. That greatest of airship enthusiasts and finest of officers, the late Air Commodore Maitland, was with them, and also Squadron Leader Colmore. Two remarks made by Mr. Ashbolt in that Midland Railway saloon over a cup of tea had impressed themselves on his (the speaker's) memory. One reply to the query of Air Commodore Maitland's was: "I do not offer alternatives; they cause delay." The other was: "I do not explain; explanations cause delay." Mr. Ashbolt, of course, intimated that he was sure of his facts, and that in both of the above cases he was dealing with a Government Committee.

If those two quotations were any indication, then Mr. Ashbolt was a man who would help to keep the British Empire together and ahead of the rest of the world by and in airship work. He was, in fact, a worthy successor to the late Air Commodore Maitland in the work of spreading the airship faith. In a paper by Air Commodore Maitland, read in that hall last year, he said:—

"A question of great practical importance in the preliminary consideration of airships is the interchangeability between the service and the commercial airship. The airship, although already developed to the stage of great utility both for service and commercial purposes, is not yet highly specialised, and its rapid conversion from one use to the other is a matter of comparative ease. The hull in both types will, for many years to come, be the same, and it is, broadly speaking, merely a matter of replacing the commercial accommodation with bombs, machine-guns, etc., to convert the commercial rigid into a most efficient service airship. This interchangeability is far more marked than in sea-going vessels. The air-ship of to-day, so far as its adaptability is concerned, should be compared to the sailing vessel of Eliza-

bethan time, ready at her country's need to become a ship of war and capable of as rapid conversion. This question of the interchangeability of the service and commercial airship is of extreme importance, as on it depends the logical and economical method of future development.

"The close association between the Navy proper and the mercantile marine has been proved beyond question an unqualified success in the Great War. The required number of surplus air personnel not required in peace, but of vital necessity in the event of war, can be kept economically in training by the existence of a commercial airship service. Economy will be essential in all matters for many years to come, and I hope I have made it quite clear that the necessary reserve of airships and personnel to meet the exigencies of war can be economically provided by a commercial airship fleet."

Mr. Ashbolt had ably dealt with the value of airships to the Navy. Mr. Rudyard Kipling had uttered the following words in Paris a day or so ago: "What our politicians do not sufficiently understand is that there are scattered throughout the whole of Europe, possibly throughout the whole world, fathers of families like myself who have lost sons in this war, and whose one common cry is 'Security.' " Britain could provide that security if she became as supreme in the air as she was on the sea, but not unless they had the brains, the men and the money (if less were wasted). They only wanted someone with the courage to say, "Go ahead." He might be permitted to say a word or two regarding R38. On behalf of the Design Staff at Cardington he begged to offer grateful thanks to Mr. Ashbolt for the report of his last conversation with their late revered chief, Mr. Campbell. He did not think any one other than themselves who were in daily touch with Mr. Campbell would ever realise how his every thought during the last few years had been of and for airships. His faith in them had been supreme, and the continual "set-backs" had been very severe blows to him, as to all. More full scale experiments had been required, and that was what was wanted to-day, and they should be the first things to be put in hand, and at once. R 38 had been essentially a service ship, and designed during the war, and great things had been demanded, and, he believed, could have been realised. She did altogether about 50 hours actual flying, and had completed over 30 hours in the air on her last flight before the tragic accident happened. With airships designed and built for commercial purposes, fine margins would not be necessary. Ships of a more robust nature would be designed—ships that could withstand all weathers and be able to live at the mast almost indefinitely. The public must be impressed with the fact that the experimental days were over. Experiments and research were, of course, necessary for improvements, as in all vehicles for transport, but an airship could be built to-day that would successfully and repeatedly accomplish the return journey to America or a journey to the Antipodes. If the German-Spanish plans matured before we got to work, they would capture all the airship traffic on terms with which we could not compete, and the nation with commercial airships and flying experience

at her disposal was the nation with the future of the air in her hands, whether it be in times of peace or the agony of war. They who believed in airships would wish for an all-powerful body to govern development on behalf of the British Empire. An airship structurally sound had little or no danger from hydrogen and could, he believed, be made immune from petrol fire. Experience of over two million miles flown during the war and since was evidence of that. When heavy oil engines were introduced those dangers would disappear altogether. The late Flight-Lieut. Pritchard, in the discussion on his (the speaker's) paper read before the Institution of Naval Architects last year, said: "I would like to emphasise, in conclusion, the importance of improving detailed design which will ensure reliability of service with existing ships, rather than proceeding with costly new construction of large rigidids of greater performance on paper. Even if the limitations imposed by the present financial situation did not exist, I would still urge the soundness of the policy of perfecting existing ships in the few vital respects which are alone necessary to make the airship of to-day truly commercial." Those of them who realised Pritchard's genius would remember his words, and hope to have the opportunity of acting on his advice and that of those who went with him, thereby in a small way perhaps doing them honour in gaining, for the British Empire, that great asset, and for the world, Security.

THE CHAIRMAN (Lord Montagu of Beaulieu) said that, having studied the subject from the Indian point of view, possibly more than from any other standpoint, he thought it would be of immense advantage to India if she could get into closer touch with Europe and especially with this country. At the present moment, by the fastest route via Marseilles, and by the best mail ships, it took 16 days to reach Bombay, the sea route being 6,000 miles. By going via Cairo and Basra, the distance was shortened to something like 4,500 miles. At 100 miles an hour, that would mean only a 45 hour journey, but even if it were a 90 hour journey, it would mean a saving of ten days. The greatest interest was being taken in the subject in India. When he read a paper not less than five years ago on the matter, he had fore-shadowed a service to India. Such a service had since really come about. There had been not only direct flights to India, but there had been flights over intermediate distances towards India. He hoped that in the future, India, as well as other important parts of the Empire would have a regular airship service. He welcomed Mr. Ashbolt as one of the most able recruits to aviation who had come forward in recent times.

LORD MONTAGU OF BEAULIEU then vacated the chair, which was taken by SIR CHARLES S. BAYLEY, G.C.I.E., K.C.S.I.

COMMANDER SIR TREVOR DAWSON, Bt., R.N., remarked that we lived to-day in extraordinary times. We still saw great armies in being on the Continent; two great Powers were still building ships and launching them, and the great British Empire at the present time had not a single ship under construction and had actually stopped even the preliminary work on four cruisers urgently needed to replace obsolete vessels. We were practically doing nothing at all with regard to the development of armaments generally for the defence of the Empire. It was a very extraordinary position; yet, having regard to the economic situation to-day, it was not a matter of surprise that the Government could not afford money for the development of the airship. He would like to add his opinion, for what it was worth, that he did not think any Fleet to-day was complete without airships and aeroplanes. That being the case and our Navy being all-important to the Empire, was it not, from the economic standpoint, the duty of the great transport companies and patriotic members of the Empire to get together and to develop the airship for commercial purposes so that such practical experience could be used by the Army and Navy, especially as they all knew that such experience was absolutely essential? That was really the point he would like to make. It was impossible to-day, in the present state of the finances of the Empire generally, to spend a lot of money, but was it not the duty of the citizens of the Empire to get together and take the matter up? There was no doubt whatever that our great engineers—mechanical, aerodynamic and others—were more than fitted to do everything that any other country might do, and we should not allow other countries to get in front of us. Our structural material and principles of design, our internal combustion engines, gas bags and other components were of the very best. It was really up to the people of the country to find the necessary money in order to organise a proper transport service so that the Navy and the Army could have full advantage of it in times of emergency.

MR. ALFRED BIGLAND, M.P., in proposing a vote of thanks to Mr. Ashbolt, said he did so in a public capacity, in that he was the Chairman of the Empire Development Parliamentary Committee. The audience would be glad to know that during the last few months a desire had grown up in the House of Commons to do all they could to enhance the development of the Empire in every direction. Before hearing the author's paper, he had been an ignoramus almost on aviation, and its possi-

bilities with regard to speed and cost. He had been intensely interested in hearing the paper, and he would take it with him to his Committee. It might surprise many to know that that Committee had grown so fast that at the present time it numbered 208 Members of Parliament. As Chairman, he had felt it was quite impossible to work a Committee of that size in a business-like way, and, therefore, it had been divided up into Committees of 15 or 20 members, each dealing with a different subject. One of those Committees was going to devote itself to that branch of empire development work dealt with in the paper, and perhaps Mr. Ashbolt would do the Committee the favour some day of talking to them in a Committee Room of the House of Commons, so that when aviation estimates came before the House, the Members might really know something more than they had been able to acquire up to the present time. The idea he had in mind was that the Empire was in the position of every other nation in the world to-day, namely, it must protect itself, it must grow within its own borders all that it needed, and that it must employ its own people in its own industries to an extent which had never been known before. The subject dealt with in the paper would be one of the most important ways of bringing the Empire together as a unit. Although he felt that the House of Commons could not pass estimates for big sums for the development of civil and military aviation at the present moment, yet the study of the matter would, he hoped, prepare them within a few years, when the finances of the world became a little more normal, to face such estimates.

MR. PERCY HURD, M.P., in seconding the motion, said if ever there was a subject which should interest the members of the British Empire it was aviation. Mr. H. G. Wells had said the other day that the British Empire could not last for very long. It certainly could only carry out its great purpose if there was a better understanding and a closer sympathy between all parts of it. On that point might he utter a word of warning, as a Member of Parliament? He appealed to everybody in the matter of airships and aircraft development, to think less of subsidies and more of self-help. Officialism had gone far to paralyse our Empire wireless developments by red tape and other obstacles, and in the matter of the development of aircraft, which was essential to the Empire, he asked the public to think less of Government Departments and to rely more on the genius of the British people for self-management and self control.

The vote of thanks was carried unanimously.

MR. ASHBOLT, in reply, said that when it was suggested to him that he should prepare the paper, he felt that it had been a very great compliment not only to himself, but to the State of Tasmania, which he had the honour of representing at this end of the world. If he had helped the British public to realise the possibilities of an Imperial Air Service, then he had been amply repaid for the little work he had done. He personally realised the opportunity for getting the Empire closer together, and he also realised the danger which must attach to our negligence if that opportunity were not taken.

With regard to Sir William Branker's remarks, the estimates certainly showed that the possible revenue pretty closely approximated to the possible expenditure, but before that possible revenue could be obtained, some little time would have to elapse, and during that educational period, the assistance of the Governments was absolutely essential. After five or six years, he believed it was quite possible that the business could be self-supporting, but in that intermediary period which required such a big amount of overhead capital expenditure, some revenue must be guaranteed to justify the provision of that capital under the present stringent conditions. He was not a believer in charging maximum fares. His experience as a business man was that if one was going to get whole-hearted support one should charge—whether it be for food products or means of communication—at approximately the same rate as existing conditions. The big bulk of the people were not prepared to pay high rates for an accelerated service. If one gave them an accelerated service at approximately the same rate, one could then command their trade; and it was with the idea of commanding trade and getting the thing on a commercial basis that he had suggested reasonable fares and not maximum rates. In conclusion he desired to thank the Royal Society of Arts for the opportunity it had afforded him to read the paper, and also Lord Montagu of Beaulieu for taking the chair.

The proceedings then terminated.

PRUNE GROWING IN SOUTH-WEST BEDFORDSHIRE.

Mr. N. J. Wood, in an article in the December number of the *Journal of the Ministry of Agriculture*, gives the following account of Prune-Growing in South-West Bedfordshire:—

The prune-growing district in South-West Bedfordshire and in North Buckinghamshire, occupies a belt of land about 14 miles long and 2 miles broad stretching from Stanbridge and

Totternhoe in the east to Aylesbury and Wendover in the west. There are some 2,000 acres of fruit in the whole district, and in the smaller area in Bedfordshire and on the borders of the two counties about 500 acres are under prunes.

In the smaller area the soil is a fairly heavy clay, mixed with which is a large percentage of lime. This soil appears to suit the prune, and the need for lime is shown by the fact that in one orchard where prunes were planted on clay no success was obtained until the soil had been heavily limed, after which the trees made excellent growth. Many growers apply lime, which is conveniently obtained from the numerous lime-works near Dunstable. The under rock is almost pure limestone, which on the Dunstable Downs often comes to the surface.

Cultivation.—The prune orchards are all under grass and do not come into full bearing until the trees are about 30 years old. Most of the orchards were planted about 40 or 50 years ago, and are therefore now in their prime; it is said that the trees will continue bearing fruit until they are 100 years old. After planting no cultivation of the soil takes place; it is found that cultivation prevents fruiting, and once the tree is formed the orchards are allowed to run to grass and are used as poultry runs, or, later, as keep for cattle and pigs. Cow manure appears to be very beneficial to the trees.

In many of the smaller orchards the trees were planted un-systematically and little attention was paid to them in their early stages, so that they are now badly-shaped and weak-bearing. Where planted systematically, however, it has been found that the trees must be given plenty of room owing to their spreading habit and the size they attain. Thirty feet square is not too much if the trees are to have full advantage of light and air. The weak spreading habit of the tree often causes the branches to bend down to the ground with an abundant yield of fruit. Some growers have permanent props for the principal branches, and these undoubtedly prevent damage to the fruit.

Once the tree is formed no pruning is done except to cut out dead wood. Even this is often neglected, with the result that in many cases large main branches have had to be removed eventually, whereas a little judicious cutting a few seasons before would have prevented the spread of the diseased wood.

As a rule, manuring is confined to the droppings of animals, but some growers apply farmyard manure or shoddy as a mulch round the trees; and as stated above a dressing of lime is often given.

Character of Tree.—The prune tree is always grown as a standard in this district and attains considerable size. The leaf is smaller than the ordinary plum leaf but larger than that of the

damson. The fruit is very similar to the damson, but much larger, and a very fine "bloom" is a characteristic which distinguishes it in normal seasons. In taste it is bitter, but its keeping qualities are excellent, and for this reason a large quantity of the fruit is dispatched for use in the Fleet. This appears to be one of its chief uses; another is that of making dyes for silken materials. So far as can be ascertained it is not used as a dessert fruit, but is largely used for culinary purposes, and owing to its lateness usually commands a good price.

Marketing.—A considerable quantity of the fruit goes to the markets in the great northern towns, but consignments are sent to all parts of the country. This season has been a very bad one: though the trees blossomed well, frost did a lot of damage before the fruit set, with the result that the crop has been practically a failure. A good season has not been experienced since 1918, when an average of about 5 tons to the acre was obtained; in 1919 about half this quantity was picked, but last year and this year only a few bushels have been gathered. A normal season yields 4.5 tons to the acre. The fruit is usually sent away in sieves and half-sieves, and as a general rule travels very well.

It is astonishing that this fine prune has not spread to other districts. There is a local belief that it does not grow well in Kent, but in all probability it has never had a fair trial. A certain number of suckers were sent to Wisbech and up to the present they are giving indications that they will do well, although their exploitable age has not been reached.

Pests.—The chief insect pest is the leaf-curling aphid which does very considerable damage in some years, a reduction of 20 per cent. in the crop resulting. Caterpillars of the lackey moth are sometimes troublesome, and a mite, which causes galls upon the leaves and renders them unsightly, is sometimes found in the older orchards, but the damage done is not sufficient to result in appreciable loss of crop.

Silver Leaf has appeared in some orchards, but few trees have been killed or have had to be totally removed. The reason for this apparent resistance is probably the vigorous growth and natural hardness of the prune; and the possible use of the prune as a stock for other plums, especially Victorias, is suggested as a method of combating the disease.

Very little spraying is done in the district, except in the best orchards. A home-made mixture containing copper sulphate and lead arsenate has proved very satisfactory. Some growers limewash their trees and occasionally spray with lime, but as a general rule, owing to the expense of the operation, the small orchards receive little or no treatment.

Journal of the Royal Society of Arts.

No. 3,606.

VOL. LXX.

FRIDAY, DECEMBER 30, 1921.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 4, at 3 p.m.
(Juvenile Lecture.) WILLIAM REGINALD ORMANDY, D.Sc., F.I.C., "Clay: What it is—Where it comes from—and What can be done with it." The lecture will be illustrated with experiments.

Special tickets are required for this lecture, and no person can be admitted without one. A few tickets are still left, and these will be issued to Fellows who apply for them at once.

DOMINIONS AND COLONIES SECTION.

The Council have appointed Mr. P. J. Hannon, M.P., Director of the British Commonwealth Union, a member of the Dominions and Colonies Committee.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

CASES FOR JOURNALS

Cases for keeping the current numbers of the *Journal* are now obtainable. They are in red buckram, and will hold the issues for a complete year. They may be obtained post free, for 7s. 6d. each, on application to the Secretary.

BINDING COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their annual volumes of the *Journal*, cloth covers can be supplied, post free, for 2s. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

WEDNESDAY, NOVEMBER 30TH, 1921.

SIR FRANK BAINES, C.B.E., M.V.O.,
Director of Works, H.M. Office of Works
and Public Buildings, in the chair.

THE CHAIRMAN, in introducing Mr. Noel Heaton, the author of the paper to be read, said he thought everyone present was aware that Mr. Heaton was a very well-known technologist and chemist, thoroughly familiar with the problems which had to be dealt with in the preservation of stone. Personally, he was very interested in the fact that Mr. Heaton had paid a considerable amount of attention to the subject of glass technology, and he hoped that some day he would enlighten the Fellows of the Society upon that question. He felt the author was a man of entirely unbiassed views and of scientific training, and that those present could rely with complete confidence upon his giving them a very clear, unbiassed and scientific view of the very difficult question with which the paper dealt. Mr. Heaton had written many admirable treatises on colours, oils and varnishes, and personally he had been enlightened in many ways by the admirable documents Mr. Heaton had published. He thought the subject of the paper was one of primary importance at the present time. There was not the slightest doubt that it had been one of increasing urgency since the nineteenth century, and when the character of the alteration in the London atmosphere in modern times, since the industrial revolution, was realised, it would be seen that the problem was going to become more urgent rather than less. He made a calculation before Lord Newton's Committee on Smoke Abatement—and he believed his figures were accepted—that there were thrown into the London atmosphere per annum, roughly 80,000 tons of sulphuric acid, and it was surprising that the stones used in London buildings could stand up at all under the conditions to-day. He had tried to ascertain whether the question of stone preservation was referred to in any mediæval or classical documents. He could find very few instances, though there were references in certain mediæval

documents showing that attempts were sometimes made then to preserve stone by oiling it, but there was no record as to the effect of that treatment. Perhaps Mr. Heaton could say what the effect of it would be. He also found that Sir Henry Rawlinson claimed to have seen a very early cuneiform inscription which he thought had been treated with some solution of silica, but it was contended afterwards that that might have been merely due to the fact that water containing silica had passed over the inscription. It was very important that a decision should soon be arrived at as to whether there was a solution to be found, and it would be a solid gain, even if it could be definitely ascertained that there was no solution, because the attention of those interested in the subject could then be turned to other matters, such as the question of the pollution of the London atmosphere and the atmosphere of other great urban areas by the distribution of sulphuric acid through coal being used as a raw material.

The paper read was :—

THE PRESERVATION OF STONE.

By NOEL HEATON, B.Sc.

The preservation of building stones is, by common consent, one of the most baffling, and, therefore, one of the most fascinating problems with which the technical chemist is faced. In bringing the subject up for discussion once more to-night, let me say frankly at the outset that I am not coming forward with any claim to have solved the problem, and to offer architects a sure and certain process for preventing and arresting decay. There are many, both amongst architects, geologists and chemists who consider that the problem is definitely insoluble, and any attempt to solve it is a waste of time. Whilst I am not so pessimistic, the more experience I gain on the matter, the more I realise the difficulties in the way of a really successful solution. It can only be accomplished by the united efforts of all concerned in the maintenance of our public buildings, and by constant exchange of experiences.

There is no need for me to enlarge upon the importance of the quest. It must be patent to everyone that hundreds of thousands of pounds are spent annually in keeping the stonework of our buildings even safe, and that, in spite of every care, our historic buildings are crumbling away. For many years past architects have been bombarded with a succession of patented or secret proprietary processes, each claiming

to be the long sought panacea, but each in turn proving of very indifferent value.

The problem is not one that should be left to private enterprise : the discovery of an efficient method of preservation is a matter of national importance and can only be dealt with on a national basis. H.M. Office of Works has fully recognised this, and has had the matter under constant observation and investigation for years. Every process that has been introduced has been given full and impartial trial, and extensive investigations have been made under their direction by Professor Church, and since 1914 by Professor Laurie. Recently, the Department of Scientific and Industrial Research has undertaken investigations, more particularly in connection with the protection of new stonework.

As yet, no comprehensive account of the results of these investigations has been published, and in the absence of such detailed information, the architect entrusted with the preservation of buildings may well be in doubt as to what course to pursue. My purpose, therefore, is not so much to propound any new theories as to survey in a concise form the present state of our knowledge of the subject, and present for criticism and discussion, my views as to what can and what cannot be done, in the hope that it may be of some little practical service.

Let us glance for a moment at the fundamental conditions of the problem. Confining the issue to natural building stones, the geological formations from which these are obtained fall into two main groups, the hard crystalline igneous rocks, such as granite, and the sedimentary rocks, which, according to the conditions under which they were deposited, range from a pure limestone, such as chalk, consisting almost entirely of calcium carbonate, to a stone consisting entirely of grains of sand cemented together by silica and containing practically no lime. Between these two extremes we have every possible variation of chemical composition and physical and petrological structure. Not to attempt a detailed description of the large range of building stones thus available, which would land me into a paper on Economic Geology rather than Stone Preservation, the following rough and ready classification of the main types of sedimentary rocks based on chemical composition is sufficient for our purpose :—

	Aggregate.	Cementing material	Example.
Limestone	Calcium carbonate.	Calcite	Portland, Bath
Magnesian Limestone	Calcium and magnesium carbonate.	Calcite	Anston.
Siliceous limestone	Calcium carbonate and silica.	Calcite	Chilmark.
Sandstone	Crystalline silica and silicates.	1. Calcite	Reigate.
		2. Iron and calcite.	Red Mansfield.
		3. Hydrated silica.	Craigleith.

Leaving out of account variations in physical structure which are at least as important as chemical composition, broadly speaking the harder and more siliceous a stone is and the less lime it contains, the more durable it is. One can generalise the order of durability as :

1. Granite.
2. Siliceous sandstone.
3. Magnesian limestone
4. Limestone.
5. Calcareous sandstone.
6. Ferruginous sandstone.

If durability were the sole consideration in selecting building stones, one might use nothing but hard igneous stones like a fine grained porphyry or granite, and decay, although it would still exist, would become a minor problem. Unfortunately, there are *many* other things to be considered. The harder a stone is the more difficult it is to quarry, and, therefore, the more expensive it is. But even apart from any question of economy, it is impracticable to use a hard crystalline or siliceous stone, except in buildings of a severe elevation, on account of the difficulty of carving anything in the nature of complicated enrichment. For the elaborate carving characteristic, for example, of mediæval cathedrals, a freestone is essential. Taking these and other practical considerations into account, granite, and even the hardest sedimentary rocks, such as millstone grit and Craigleith, can only be used in a limited degree, and the great majority of stone buildings of to-day—and a still greater proportion of mediæval buildings—are constructed either of limestone or sandstone, the particular quality used depending on the locality and the limitations as regards transport.

The question of decay and its prevention, therefore, largely centres round those particular types of stone.

So far, I have referred to the matter as one of preventing decay in new stonework, but there is another and still more difficult problem involved. It is with this wider aspect, that of preserving and maintaining the fabric of buildings already suffering from decay with which I have been more particularly concerned. You will notice that I do not specify ancient buildings in this connection, because it is on record that many modern buildings have suffered badly from the ravages of decay. It is on record, for instance, that the condition of the Houses of Parliament was such as to cause serious alarm within twenty years of their erection, notwithstanding that at the time of building the selection of the stone, and method of construction, was made the subject of most exhaustive enquiry.

Let us enquire briefly into the causes of this decay. The disintegration of building stone arises from several distinct causes which may operate simultaneously, each increasing the effect of the other. In the first place, there is the *natural* disintegration, which takes place in all rocks on prolonged exposure to ordinary conditions of country atmosphere. The effect of rain on a sound homogeneous stone is to produce a surface weathering which adds to its beauty, but in highly absorbent stones of uneven texture absorption of moisture combined with subsequent frost, causes disastrous flaking. Violent fluctuations of temperature result in minute cracks where the stone is composed of minerals which vary in expansion. Wind causes considerable disintegration, more particularly in sandstones, by mechanical erosion. Along the coast the effect is more rapid, owing to the presence of alkaline salts. Disintegration is also caused by direct oxidation in the case of ferruginous sandstones, the iron salts which form the cement oxidising and losing their binding power, so that the stone

crumbles. This is particularly the case with some stones containing sulphur compounds, such as *marcasite*, which oxidises to form soluble salts.

The effect of these natural agencies is accelerated by irregularity of structure, such as bands of varying hardness, which cause flaking by uneven absorption of water. Still more disastrous is the irregularity of structure caused by invisible cleavage planes caused by diagonal pressure in the original rock, due to earth movements. A well known case of this is the Anston stone used in the Houses of Parliament. This stone was at one time traversed by minute fissures running at an angle of about 60° to the natural bed. These cracks have been subsequently cemented up by infiltration, and are quite invisible in the quarried stone, but they form planes through which water can more readily percolate. The result is that, sooner or later, the stone splits along the line of weakness and comes away bodily.

There are cases, again, in which stones differ in durability for reasons which are, at present, obscure. The difference between Bath and Portland stone is an example. The chemical composition is almost identical, both are oolitic in character, and there is little difference in structure to account for the notorious difference in durability. We have, in fact, still much to learn as to the influence of minute differences of physical structure in natural building stones. It has been suggested* that the presence of a small percentage of soluble salts in the original stone may influence its durability, and careful research on points like this may throw much light on the problem of preservation.

The growth of vegetation on stones is another peculiar point—some stones are affected in this way more than others, for no apparent reason. The growth of vegetation in most cases accelerates decay, particularly when it takes the form of mushroom like patches, which act like a sponge, keeping the surface damp. The development of lichen on stones, is, however, in many cases actually beneficial. Those minute lichens which one finds covering old buildings with flat, closely adherent plates, I regard as a natural preservative. They tend to shed rather than absorb water, and they certainly act as a buffer to the erosive action of the wind. It is

fortunate that one can regard them in this light, as I think everyone will agree that they enhance the beauty of the stone in a way that no art can achieve. The action of micro-organisms has been suggested* as playing a part in the decay of stone, but whilst this is a possible contributory cause, I do not consider myself that it is a primary one, the organisms being present rather as a result of decay than causing it.

I pass from the natural to the *unnatural* causes of decay; using this term in the same sense that you speak of a man leading an unnatural life who spends his time in the close confines of an unhealthy slum. It is unnatural for a building to suffer the ravages of that peculiar product of modern civilisation, the urban atmosphere, which is essentially an extreme dilute solution of sulphuric and sulphurous acids.

The action of sulphuric acid, coupled with the accumulation of soot and grime, is the most potent cause of decay at the present time, although we can safely say that we have passed through the worst, and may look towards the future with a certain measure of hope. There is still another contributory cause to decay, which I will call faulty construction. For instance, it has been an axiom in building from time immemorial that a stone should always be laid in its natural bed, for reasons which a rudimentary knowledge of geology renders obvious; ignoring this axiom by "face bedding" the stone increases the rate of decay enormously. The use of iron dowels and cramps is another well recognised cause of splitting and flaking of stonework, owing to the strain set up by the rusting of the iron.

I now show you a few typical examples illustrating the effect of these various destructive agencies, and so pass on to consider what can be done to minimise their effect.

To consider, first, the case of prevention of decay in new buildings. I trust I have made it clear that we are constrained to use materials which are naturally prone to decay, and the first and most important consideration is that one must recognise this, and give them every possible chance, both in the design and construction of the building. I am not going to presume to discuss the influence of design, but I refer again to the fundamental importance of careful selection of the stone to secure the

*A. Lucas.—"Disintegration and Preservation of Building Stones in Egypt."

*Dr. Tempest Anderson, Yorkshire Philosophical Society, 1910.

maximum possible durability, and careful supervision to ensure that it is laid in its natural bedding plane, except in exceptional cases where the design of the building precludes this. It may seem ridiculous to even mention this obvious point, but my idea that you never find a face-bedded stone in a modern building has been very rudely dispelled by a tour round some of our most important public buildings. I have been astounded at the number of face-bedded stones—even in the case of sandstone, where this is most disastrous—in some of our important public buildings erected during the past century. Of course, in a stone of very uniform texture, such as Bath, it is a matter of some experience to identify at sight the correct bedding in the freshly cut stone, and it may, therefore, seem unimportant, but exposure will always in the most heartrending manner demonstrate that this is not the case. Another indirect method of preventing decay is to further, by every possible means, the campaign for the purification of the atmosphere from the products of combustion of fuel, particularly as regards sulphur compounds.

Treatment of stone with protective solutions is the final link in the chain. No preservative has yet been discovered which will give Bath stone the endurance of granite, which is the ideal we aim at. At the same time, in my opinion, treatment is distinctly beneficial provided that the preservative is of known composition, adjusted to the character of the stone and the conditions of exposure, and applied under proper supervision.

The preservation of old buildings where decay has already taken place is infinitely more difficult than the protection of new ones—we have to take the building as it stands, and do what we can with it. In ancient times difficulties of transport rendered the choice of stone more limited. Unsuitable local stone was often used, and it was often badly selected and badly laid. Little precaution was taken to prevent the access of damp, and the designers, naturally, did not provide for the drastic conditions which prevail in modern times.

We have to bear in mind also that, up to a certain point, the weathering of stonework is a distinct advantage—we do not wish to destroy the time-honoured effect of old buildings any more than one would want new buildings to resist the

mellowing effect of time. The drastic restoration of old buildings, the ruthless removal of every sign of decay and conversion to a bright new structure, is rightly deprecated at the present time. *So long as one possibly can*, the right thing to do is to leave an old building alone.

But when the effect of time passes, the limit of "a perfecting by God of the hand-work of man," and decay becomes unsightly and unsafe, something has simply got to be done to arrest it, and to re-construct the already decayed stone. That is where the search for a reliable preservative which will protect the building without in any way detracting from its beauty becomes of paramount importance.

The properties demanded of a perfect stone preservative are many and conflicting, and may be briefly tabulated thus:—

1. It must penetrate easily and deeply into the stone, and remain there on drying.
2. It must not concentrate on the surface so as to form a hard crust, but at the same time, harden the surface sufficiently to resist erosion.
3. It must prevent penetration of moisture, and, at the same time, allow moisture to escape.
4. It must not discolour or in any way alter the natural appearance of the stone.
5. It must expand and contract uniformly with the stone so as not to cause flaking.
6. It must be non-corrosive and harmless in use.
7. It must be economical in material and labour of application.
8. It should retain its preservative effect indefinitely.

In discussing the present state of our knowledge of stone preservatives, it is hopeless to attempt to describe individually the principles and merits of the numerous proprietary articles which have been placed on the market in recent years; it would take a long time, and would not lead us very far.

You may not agree with me, but, personally, I object to the use of any material of unknown ingredients, and consider that the problem can only be rightly tackled by employing only substances of known composition under principles worked out by a chemist so that the method of application can be controlled. Even failure is not waste in this case, because at least you

have added a definite fact to experience, and it is only by the accumulation of such data that we can ever hope for progress. To make trials with preparations the composition of which is jealously guarded as a secret is, however, useless, because we can learn nothing from failure—we may, as a matter of fact, be experimenting with the same thing over and over again, because, in my experience, many of the proprietary articles are materially the same thing under a different name.

Careful study of the data concerning every process that I have been able to discover shows that, as regards the principles on which they act, they can be roughly divided into three groups :—

1. Those which only act as surface coatings.

2. Those which impregnate the stone without chemical action on it.

3. Those which operate by chemical reaction with the stone.

In the first category, we may place paint and limewash. The most durable paint—and here, perhaps, I am inviting controversy by implying paint made with white lead—undoubtedly acts as a fairly efficient preservative, but not, unfortunately, in the sense that we require, because it obliterates entirely all that quality of surface and texture which is the chief charm of a stone building.

Limewash has, however, been used from time immemorial as a protective coating, and is still largely employed. When properly made with boiling water so as to ensure the maximum quantity of soluble hydrate of lime, it can, to a certain extent, consolidate the friable surface of partly decayed stone, and it retards decay to a certain extent by reacting with sulphur acids and neutralising them before they can reach the stone beneath. Its effect in this direction is, however, only temporary, and to be effective it requires frequent renewal. This has the objection that being a surface coating, repeated applications tend to obliterate the details of any enrichments of the surface, and it can at best only be regarded as a temporary expedient. Limewash has the advantage of economy, and can be safely used in many cases in the absence of a more perfect method, more particularly in situations where it can readily be renewed, and where the stone is subjected to a moist atmosphere but protected from direct rain. I mean, for

instance, cloisters, where there is no direct washing effect, but where fog, which of all things is the most harmful because it contains the maximum of corrosive acids, has free access.

The second class of preservatives are those which operate on the principle of impregnating the surface of the stone with a material which prevents the penetration of moisture, and is highly resistant to chemical action. The most obvious material to use for the purpose is mineral wax, which is composed of solid hydrocarbons. Hard paraffin wax is highly resistant to the action of acids, and is impervious to moisture. A solution of wax in benzene or similar organic solvent, has formed the basis of many preparations, disguised under some fancy name.

In theory, a preparation of this type will penetrate the surface of the stone, and render it impervious and resistant. It is, in fact, quite easy on a small scale to produce this penetration, and to demonstrate that the surface, so treated, is consolidated and rendered immune from decay. In practice, however, on the large scale, this theory does not work out. In order to allow penetration of a substance which will not mix with water, it is necessary for the stone to be absolutely dry, a condition which rarely obtains in this country in a building exposed to the weather. Wax is, moreover, only sparingly soluble and a liquid preparation of this kind only contains a small proportion. The result is that on application the solvent rapidly evaporates and deposits the wax as a loosely coherent film on the surface, which soon scales off and does not efficiently protect the surface.

A more hopeful method of applying wax is to drive it in by means of heat. This encaustic process is one of the most ancient methods of water-proofing a surface. It was introduced by the Greek artists, not so much for preservative purposes as for giving a polished surface to painted plaster, as, for example, at Pompeii. The late Professor Church's method of encausticising was to make a paste of ceresine wax and toluol, about the consistency of vaseline, spread this in a thin layer on the stone, allow the solvent to evaporate and then melt the wax by local application of heat, when it soaks into the stone.* A similar process has been employed by Dr. Caffal in America—notable for the treatment of

*Conservation of Urban Stone-work : R. Institution, 1907.

the Obelisk in Central Park, New York. This treatment is undoubtedly effective for certain purposes. For the protection of mural decorations in fresco and tempera it is very useful, and I have employed it myself successfully for that purpose. I consider it useful also in certain cases for the protection of delicate carved stonework which is shewing signs of decay. But for general use on buildings, especially for exterior work, it has fatal objections. Its effective application is slow, and requires skilled labour, so that it is extremely costly; moreover, wax, unfortunately, softens in hot weather with the result that dirt adheres to it, and the treated surface becomes very unsightly. Again, as it is practically impossible, on the large scale, to ensure that the stone is perfectly dry before application, the effect of forming an impervious coating on the surface area is that in hot weather the moisture locked behind it develops sufficient pressure to burst through, causing disruption and flaking.

The one outstanding feature of the encaustic treatment is that you *can* drive the material well into the stone, and get penetration, which is the great stumbling block with all methods in which the preservative is applied in the form of a solution. Professor Laurie has clearly demonstrated* that even when application of the solution results in penetration to a considerable depth, it by no means follows that this penetration remains at the finish, because, as the solvent used to reduce the protective agent to the mobile liquid necessary for penetration evaporates, the preservative is drawn back to the surface by capillary attraction, and finally forms merely a thin coating on the surface, which tends to scale off.

The next group of preservatives in this class are those in which drying oils or fatty acids are the principal ingredients. According to Professor Laurie, linseed oil, reduced to the requisite viscosity with a volatile thinner, fulfils better than any other solution the most essential condition of penetrating the stone. Impregnation with boiled linseed oil has long been practised; it has, however, the disadvantage of causing discoloration and is not chemically stable, gradually oxidising and becoming friable. The durability can be increased by sulphonating the oil by heating it with sulphur, a process for which Daines took out a

patent in 1854. This preparation has been used both for impregnating stones before fixing, and treatment of partially decayed work. The results of treatment are in general successful, from the point of view of protection, but disastrous from an æsthetic point of view, owing to the discolouration. This material could be used with advantage for dark ferruginous sandstones, but for a stone like Portland, it is hopeless. A more satisfactory oil preparation has been used for some time in America, in which linseed oil is replaced by Chinese wood oil, reinforced with rosin and fatty acids.

As far back as 1850, however, Sylvester endeavoured to secure better durability by using saponified linseed oil in place of the oil itself; this being miscible with water penetrates the stone more easily. His method was to dress the stone first with a solution of alum in water, followed by a solution of soft soap, both being used as hot as possible. As a result, the aluminium salt of the fatty acids is precipitated in the stone, and this is insoluble and tough, and forms a consolidating or binding agent in the stone. It has the disadvantage of forming potassium sulphate as a by-product of the reaction, although this does not cause serious efflorescence. It cannot be relied on for protection for more than a few years, when re-dressing is required, but it certainly consolidates decayed stone and does not cause discolouration. Up to the present, no more satisfactory material of this type has been produced, and it has the advantage of being very economical and easily applied. I prefer it, therefore, to other organic preparations for the re-consolidation of decayed stone, although it is by no means a perfect preservative.

Numerous other organic impregnations, such as creosote, casein and solutions of resins in alcohol have been tried without much success. Professor Laurie considers that the most hopeful line of progress lies in the direction of a suitably prepared solution of resins, but his final results in this direction are not yet available. Meanwhile, one may say that all organic preparations at present known may be grouped together as effective for a limited period, but failing to give a permanent protection owing to decomposition.

Another group of preservatives employs the principle of depositing an inorganic precipitate of a gelatinous character in the

*Journal of the Society of Chemical Industry, May, 1918.

stone. Various salts, such as aluminate of potash, barium phosphate and barium sulphite, have been tried, but always with the result of forming a crust on the surface as the solvent dries out and causing scaling.

To come to the third class of preservatives, those which react chemically with the stone, I will mention first the baryta treatment, associated with the name of Professor Church, with this proviso, that I consider it stands in a class by itself, as not so much a preservative as a corrective or re-constructive agent only applicable to one specific case, that of a stone that has been disintegrated by the action of sulphuric acid. As a preservative on new stone or stone which has suffered what I have called natural disintegration, it is quite inadmissible. I want particularly to emphasise this, because I find by experience it does not seem to be generally understood. When a limestone or calcareous sandstone is exposed to an atmosphere containing sulphur acids, disintegration occurs, owing to the formation of calcium sulphate. Barium hydrate, which is an alkaline substance somewhat similar to caustic soda in its properties, will react with the calcium sulphate to form the highly insoluble and inert material barium sulphate. At the same time, it sets free the lime as calcium hydrate, which by absorption of carbon oxide from the air reconstitutes the original binding cement. Considered in this light, it is obvious that, unless sulphates are present in the stone, its application is useless, and that it does not protect the stone from further attack. In my own experience, whilst I have frequently found as much as 20 per cent. of calcium sulphate in interior stonework subjected to the prolonged effect of gas lighting and heating, I have rarely found more than 3 per cent. in the decayed stone of exteriors, where it is exposed to the washing effect of rain. I attribute this to the fact that the sulphates being freely soluble in water are dissolved and washed away as they are formed, so that baryta treatment seems to be in general quite useless for exterior work.

But I consider this process distinctly serviceable for special and limited application, and occasionally advise its use for special purposes, notably in the interior of buildings where carved work or mouldings have become soft and powdery on the surface, owing to the employment of gas lighting. It must be used with moderation, the

amount of sulphates present in the stone determined by analysis and the strength of solution adjusted accordingly. Used in excess, it undoubtedly does more harm than good, because the excess of barium salt rapidly carbonates on exposure to the air, forming a hard crust of barium carbonate which scabs off owing to difference of expansion. Its too enthusiastic use on all kinds of stone, particularly on exteriors, is positively dangerous and is, I consider, largely responsible for the fact that the process is generally discredited now.

To pass on to the chemical preservatives proper, the principle underlying the majority of preparations of this nature is the deposition of silica or silicates to reinforce the natural cement of the stone. The earliest attempts in this direction consisted in dressing with a solution of sodium or potassium silicate, popularly known as water glass, which is gradually converted into insoluble silicate of lime by reaction with the stone. But in any process involving a chemical reaction, it is essential to take into consideration the bye-products of that reaction. In the case of water glass, the result of this action is to liberate caustic alkali, the effect of which is disastrous, producing unsightly efflorescence and rendering the stone hygroscopic.

Attempts were made later to minimise this effect by alternate dressings with water glass and calcium chloride, which is well known to react with sodium silicate to produce calcium silicate together with colloid silica. But the result of this treatment is to produce common salt as a bye-product, which is not at all desirable. The use of calcium chloride as a precipitating agent has the added disadvantage of being deleterious if used in excess. Owing to its well-known property of attracting moisture, its presence in the stone tends to keep it damp. A more hopeful method of using silicates is that due to Mr. Hemingway, who proposed to dress the stone first with a weak solution of water glass and then with a solution of arsenic acid, which reacts with the silicate of soda and the stone simultaneously forming a precipitate of gelatinous silica and arsenate of lime which acts as a binding agent. This process has been extensively used, and gives fairly satisfactory results, but the difficulty with it is that the reaction takes place at the surface with the result that a hard surface skin is formed which peels off after a few

years' exposure. This process also does not obviate the difficulty with all water glass processes that alkali is released as a by-product of the reaction, which is liable to cause unsightly efflorescence. Many attempts have been made to introduce soluble silicates into stone without using alkali, but little progress was made until in 1883, Kessler* introduced the use of fluosilicates in France. By the combination of silicic acid and hydrofluoric acid, one obtains an intermediate product known as hydrofluosilicic acid, which has the peculiarity that it forms soluble salts with magnesium, zinc and aluminium. By this means one obtains a siliceous solution entirely free from the objectionable alkali. On treating limestone with such a solution of magnesium fluosilicate, the following reaction takes place :—

that is to say, that the fluosilicate forms with the lime, fluor spar and free silica, the only by-product being carbonic acid.

Magnesium fluosilicate has been manufactured in France for many years, and is imported into this country and supplied under the abbreviated title of "Fluate." The process has been in use here for some 30 years, but the results obtained have been very conflicting. Whilst in some cases it appears successful, in most instances it is considered to have no appreciable preservative effect and to result in the formation of a hard surface skin which causes flaking. Sir Frank Baines has kindly given me facilities for examining some of our public buildings where Fluate has been used, and I must confess that I am not quite as pessimistic about the results as the Office of Works. Whilst decay has certainly not been prevented to the extent that has been claimed for it, I certainly think it has proved beneficial to some extent, and that the scaling of the surface is exceptional.

In France, fluosilicate treatment has been practised for years on Government and other buildings, and the results are considered satisfactory. Fluosilicates are also manufactured in the United States for use as a stone preservative, the double salt of magnesium and zinc being mainly used, with generally satisfactory results.

A possible explanation of the comparative failure of this process in this country may be that the method of application recommended, which is broadly to dress the stone first with a 15 per cent. solution, followed with a 35 per cent. solution, is not adjusted to the conditions of exposure here.

The use of fluosilicates, and particularly the point of the method of application has recently formed the subject of investigation by Professor Desch in conjunction with the Department of Scientific and Industrial Research. After carefully surveying the buildings treated in France, and confirming the fact that the treatment appeared to be successful, he examined the process as used here. Unfortunately, his detailed report has not yet been published, but I gather that his conclusions are, in general terms, that the solution is generally used too strong, and that a single specification cannot be used for all cases—the strength of the solution (which should never exceed 10 per cent. for first dressing), and the mode of application should be adjusted to suit the particular stone and conditions of exposure.

These conclusions coincide with experience in the United States and are, at least, suggestive that the scabbing and scaling reported in some of the fluted buildings in this country is largely due to a hard surface coating having been formed by using too concentrated a solution. Like every other preservative, fluosilicates cannot be used indiscriminately on every kind of stone. The process is most suitable for pure limestones of uniform texture, such as chalk or Bath stone, where the solution can act on the aggregate. For sandstones I consider it of doubtful value, as the action of the solution is limited to the cement. Professor Desch claims that previous dressing with a saturated solution of lime water, renders treatment successful in such cases, but I confess that I am sceptical on this point.

I consider also that the principal value of fluosilicates is as a preventive treatment on new work. As a preservative on stone already decayed and powdery, it is of less value, as the consolidating substances are not sufficiently tough to form a good cement. Although the use of any material which reacts chemically with the stone is condemned by some authorities, notably Professor Laurie, the use of substances of the

*Comptes Rendus, 1883-86, 1317. See also C. H. Desch, Journal of Society of Chemical Industry, April 30th, 1918.

nature of fluosilicates seems to me to be the most promising line of research, although it must be confessed Kessler's process, as at present used, cannot be regarded as anything approaching a complete solution of the problem.

The possibility of impregnating the stone direct with soluble silica has also been investigated, but the process is very slow and tedious—for treatment of small details it is practicable, but for general application is quite out of the question.

This concludes a very condensed summary of the principal attempts that have been made to solve this important problem. Not the least of the many difficulties in the way of research is that of finding a method of testing the value of a process with any approach to service conditions. Accurate measurements of water absorption and crushing strength give an indication of the water-proofing and hardening effect, but it is difficult to interpret the results of such tests on small samples in terms of weathering on a large scale, with all its complicated factors.

Various methods have been tried for determining the effect of weathering artificially. Professor Dodge* some time ago proposed to determine the resistance to natural weathering by suspending test pieces of known area and weight in water through which a stream of carbon dioxide was passed and determining the relative loss of weight. Professor Laurie† recommends placing similar test pieces under a bell jar in which they are subjected to the fumes of hydrochloric acid for a given time, and determining the loss of weight. Dr. Desch utilises the atmosphere of an ordinary laboratory fume cupboard in a similar manner. I have attempted myself to produce an "accelerated atmosphere" by exposing the stone to water vapour under pressure in an autoclave, and determining the effect under known conditions of temperature, pressure and time of exposure. Such laboratory methods, applied to service conditions, are in general unsatisfactory. On the other hand it is impracticable to determine the effect of varying the method of treatment and application by making exposure tests and waiting ten or twenty years for the results.

We can, however, pretty well make up our minds to one thing—that we are not

likely to discover a process for converting a soft limestone into a material which will resist all the agencies of decay indefinitely, and be capable of universal application to all kinds of stone under all conditions of exposure.

The preservation of stone probably always will remain a matter of careful supervision; the utmost we can hope for is to be able to prevent decay for a considerable period by treatment varied according to the nature of the stone and the conditions of exposure, and at present we are far from even being able to do that.

But whilst progress is thus slow and uncertain, the decay of our historic buildings is quite the reverse. Something has to be done, and it is on the principle that it is better to do what one can at once than wait for the millennium, so slow in coming, that I have attempted in this paper to review the present situation and express my views in the hope that they may be of some practical assistance to the architect.

Let me now summarise for criticism and discussion the conclusions I have arrived at:—

1. New work can be rendered to a certain extent more resistant to decay by treatment with fluosilicates, provided the strength of solution and method of application is adjusted to suit the stone used.
2. No preservative treatment will be effective on faulty or face bedded stones.
3. Constructional methods of reducing decay (prevention of damp, effective carrying away of storm water, etc.), are more important than preservative treatment.
4. For outside work on old buildings no preservative at present known serves to preserve decayed stone for more than a limited period. The most economical treatment is dressing with soft soap and alum, renewed every few years.
5. In interiors, where the stone has been corroded by sulphur compounds, baryta treatment is, in many cases, beneficial, but it should only be used with restraint and under careful supervision, and should be followed by distemper.
6. Preservative treatment should only be employed where it is certain that it can, at the worst, do no harm. For this reason articles of unknown composition should be avoided, and only materials used the action of which is well understood.

†"The Builder," October 15th, 1920.

Progress towards the goal can only be obtained by constant exchange of experience and study of results. That is the line I have pursued, and I want, in conclusion, to express my gratitude for the unfailing assistance I have received from the many to whom I have applied to check the results of my own experience. In particular, I have gratefully to acknowledge that this paper would have been a very sorry affair without the support of Sir Frank Baines, who has placed all the resources of H.M. Office of Works at my disposal for collecting and checking information. The majority of illustrations and specimens I have been able to show you have also been placed at my disposal by the Office of Works. In short, the generous encouragement that has been showered upon me cannot be over estimated.

DISCUSSION

THE CHAIRMAN (Sir Frank Baines, C B E, M V O), in opening the discussion, said he was sure all those present would agree with him that they had been privileged to listen to a paper of a most distinctive quality. It had been admirable in the way it had brought forward for review the vast area of the problem of the preservation of stone, and it had been admirable also in the conservative point of view from which the author had approached the problem and in the scientific reserve with which he had appraised the various proprietary preservatives which had been put upon the market. The first point he wished to mention was that architects, people dealing with construction, had in the past been in the habit of regarding stone as a permanent material, but stones were not permanent materials; in their very structure was the essence of decay. The early igneous and volcanic rocks had been corroded and broken down and had been the parents of the later sedimentary rocks, which had in their turn been broken down and reconstructed, and it was, therefore, essential to recognise that stones were entirely impermanent in their character and structure. When the atmosphere in great urban areas at the present time was also taken into consideration, it would be realised that it was extraordinarily difficult to evolve a solution of the problem of the preservation of stone. It seemed to him quite clear that the character of the decay was of special importance. The author had referred to the character of the decay of the magnesium limestone of which the Houses of Parliament were built. In that case apparently the utmost care had been taken to select a stone which would resist the effect of the London atmosphere, but the result had been a complete failure. That had to be attributed to the inadequate

way in which the attempt was made to deal with the subject in a scientific manner. There were two problems to be considered in that connection. One was the surface decay of the stone, due to the action of sulphuric acid and sulphurous gases on the magnesium carbonate, which resulted in sulphate of magnesium being formed on the surface of the stone. The particular difficulty occurred, to which the author had referred, of the stone being subject to minute strata of foreign material across its bed. With regard to that it was surprising to find across those strata, far removed from the surface of the stone, a very fine deposit of pure sulphate of magnesium, showing that the decay had gone on right in the middle of the stone, that the weathering qualities of the atmosphere had been such that they had penetrated the lines of cleavage and disintegrated the stone. The problem was an appalling one, and if it was dealt with drastically, tens and even hundreds of thousands of pounds could be spent on it. He thought it was due primarily to the London atmosphere and in part to the fact that those responsible had been so ill advised as to select a magnesium limestone, which he thought in the London atmosphere was infinitely more dangerous than a pure limestone. The Office of Works had attempted to collect data with regard to the subject, and sent a very detailed questionnaire to the British Ambassadors in France, Germany, the United States, Italy and Greece, with practically no result, which showed that there was very little collated information on the problem abroad. He thought the author had shown that there were more collated data in this country than anywhere else. When it was found there was very little information to be obtained from abroad, the Office of Works finally decided that as a Department they could only put themselves in the hands of the specialist. It was their invariable practice to do that when they felt they could not tackle a problem themselves. They relied upon Dr. Church's method of treating stone with baryta water, thinking they had got the considered opinion of a fine scientific brain, which would give them the solution. The author had referred in his paper to the methods adopted in applying the baryta treatment, and the criticism he made was quite a legitimate one, but the application was directed entirely by Dr. Church himself. It was Dr. Church's own view that perhaps a too partial treatment would not give satisfactory results, which, it had to be pointed out to him, were not obtained. The decay of stone was generally due to the formation of sulphate of calcium on the surface of the stone, and that material when it was formed had practically an increase of 150 per cent. in volume over its form as calcite. It was, therefore, by the very act of crystallisation and expansion in volume inevitably liable to cause exfoliation of the surface of the stone, and there was not the slightest doubt that Dr. Church's baryta

treatment would cause exfoliation, because, by turning the calcium sulphate into an insoluble barium sulphate, it again reduced the volume by the formation of the barium sulphate and exfoliation occurred. He, therefore, felt that in no case could it be logically expected or believed that the Baryta treatment would lead anywhere, and the Office of Works had entirely discarded it at the moment. They then asked Dr. Laurie to investigate the problem with them and attached very drastic conditions to the investigation, conditions which probably no other authority would impose in putting the problem before a specialist. They said that they were so subject to criticism, not only because of their bureaucratic standing, but also because of the undesirable things they were so liable to do, that they were not prepared to deal with the problem of stone preservation if it involved taking any single fragment from the decorative stone work which had been placed in their care as a national charge. They, therefore, said they would have no solution which would lay down as a principle that the work had got to be scraped or wire brushed, or—as he remembered the manufacturers of a certain proprietary article wanted him to do—that they had to chisel back to the hard work and then apply the preservative. Dr. Laurie accepted those drastic conditions so thoroughly that in certain work that had to be done on a building of great historic interest, he decided not even to spray the stone heavily but to treat it by flicking the solution he used on to the stone with a camel-hair brush until it was absorbed. It was absolutely necessary to lay down conditions which would ensure that the stone should not be treated in any other way than with the utmost reverence. The Office of Works had examined, with the assistance of their specialist, about 60 proprietary preservatives. Of those, 28 came under the category of those which acted chemically upon stone and 32 came under the category of those which filled up the open pores of the stone. It was found, on the advice of the specialist, that there was really very little hope in respect of any of those preservatives, bearing in mind that the aim of the Office of Works was to finish with the buildings for at least a decade or so and leave them to the mellowing hand of time, without continually touching them up. The author seemed to imply in his paper that the minute growths of lichens and mosses on stone were not really detrimental to it, but personally his experience had been that those minute growths did actually disintegrate stone, and he could bring forward most direct evidence of that. The Office of Works, however, did not propose to eliminate them altogether; ivy and the major destructive influences must be eliminated, but they did not advocate the elimination of lichens, mosses and moulds, which added so much to the beauty and character of old buildings. The problem of the Office of Works was mainly how to preserve with the greatest degree of care

the beautiful historic buildings which were handed into their charge for the delight and interest of future generations, and he was afraid he did not take much interest in any method of treatment which could only be used effectively in the case of new stone. When he was told that the fluate treatment might be effective on new work it did not interest him very much and he was not prepared to argue whether it was a material contribution to the subject. Another point he would like to bring forward, was whether the whole question of stone decay had been fully investigated from the petrological point of view, whether it was certain that the maximum advance in the whole enquiry had been made on that ground. He felt that if micro-photographs of the thin scale and surfaces of various stones were to be taken, and their structure ascertained from the point of view of physics, as well as of chemistry, more data would be obtained as a guide in any future action taken with regard to the preservation of stone. He thought too little had been done in that connection to warrant the statement that the subject had been exhausted. Another important point was one which the author emphasised more than once in the paper, namely, the tremendous importance of making architects realise the need for placing the stone in position in a proper and adequate manner. That was of enormous importance, in his opinion, because it must be realised that stones were impermanent in their character, and it was necessary to try to re-produce in buildings, if possible, the conditions under which the stones were deposited in the quarries, so as to render them as stable as possible. Whether that could be done adequately or not was a point to be questioned. Stones in the quarry were subjected to tremendous lateral and overburdening pressure; and when they were taken out it was found that some had quarry sap in them and some were hardened up and weathered when they were removed, and they were put into buildings under varying conditions and expected to stand satisfactorily. As an example, York stone was used to-day that was subjected to enormous superimposed pressures in the quarry, and when it was put into plinths and parapets it split and clove, mainly because of the relief of pressure and not because of the sulphuric acid content of the atmosphere. Granites themselves were subject to very material decay. In walking round the great granite cliffs of Cornwall, he found the most distinct signs of breaking down of the granites by the pure air, the granite rocks of those cliffs showing all the particles of quartz entirely separated, and the felspar was apparently entirely disintegrated and broken up, probably partly by the action of the pure rain water, which in itself was a solvent, and partly by the action of carbon dioxide on the felspar and the mica. With regard to another stone which was supposed to be a most permanent and solid

one, Craigleith stone, he saw in Edinburgh many signs of the decay of that most admirable weathering stone. With such a small proportion of pure calcite in the stone, he did not think the decay could be due to sulphuric acid in the atmosphere, but he thought it must be the result of temperature stresses. When a stone was being dealt with in which the crystals were associated together in the most dense and solid form, there was very little room for expansion and contraction under temperature stresses, and that was probably the cause of the breaking up of the stone. When such stones as granite and Craigleith broke down under mechanical actions of temperature stress and wind erosion, and so forth, it seemed to him inevitable that the other stones, containing, as they did, an agglutinant and an aggregate of pure carbonate of lime, would be broken down by the atmosphere in this country to-day, and it was, therefore, very important to deal with the question of purifying the atmosphere by resolution of the crude coal problem. The difficulty he had, as an empiricist with little chemical knowledge, was to understand how there could be any solution which would turn a soluble sulphate of calcium into an insoluble salt of some kind, and yet remain on the work married back to the stone without exfoliation? He did not think it possible that in turning soluble sulphate—increased in volume, in the case of magnesium limestone, to the extent of about 400 per cent in the act of crystallisation—back to an insoluble material the question of stone preservation would really be dealt with. He felt that every conceivable solution had been dealt with and that the physicist must come into the question far more than he had done in the past. With regard to the methods adopted for stone preservation which were of a greasy character, Dr. Laurie did very valuable work for the Office of Works in investigating capillary phenomena in the pores of stones, and showed quite definitely that, owing to conditions of the surface tension of the material, where the solutions applied to the stone were of a greasy character there was an inevitable result that the whole of the solute of the material returned by capillary attraction to the surface layer of the stone. The author brought out that point very clearly, but what Dr. Laurie said was that unless the question of surface tension was further investigated he was not prepared to say that any solution would do other than return its solute to the surface of the stone, particularly when the stone had been subjected to the greasy atmospheric deposits of a large urban centre. If that was so, it was perfectly clear that that aspect of the problem must be dealt with first, and if it could not be solved it would be found that the stone scaled on the surface, because of the purely capillary phenomena. He felt it was most dangerous in the question of stone preservation to deal with any method which postulated that

the solution would attack the natural agglutinant of the stone itself. Nature provided a particular agglutinant for certain stone, which happened to be calcite, and yet people were prepared to break down that calcite and put something else in its place. He was perfectly certain that disaster would follow that method. The Office of Works was investigating methods of dealing with the preserving of decayed stone by using organic substances, and he thought the chemist ought to say something about that. He could not conceive in his own mind that organic substances were ever likely to be in any way permanent in the sealing back of the disrupted particles of decayed stone. Dr. Laurie had pointed out that certain organic substances such as ambers and resins, were very stable, but he thought it was very doubtful whether those ambers and resins would remain in the stone without altering its character. That was a point on which the chemist might be able to give information. He came across one very interesting fact in looking into the question of stone preservation, and that was in the various researches made by Dr. Tempest Anderson in 1910. Dr. Anderson considered that decay was caused partly by organisms similar to moulds and fungi, for which dirt and damp formed a developing nidus, and he definitely produced thousands of colonies of unidentified bacteria which he was not in a position then to say were detrimental, but he rather considered it inevitable that they would be detrimental. That was a line of enquiry which ought to be pursued, and it bore materially on the point brought out by the author, that he would prefer to see the minute lichens remaining on the stone. There was another point that should be brought out very clearly. He had seen stones that had been pointed, stones of very old buildings, and the pointing had been kept back from the surface and the decay had gone on, and the modern pointing put in to preserve the joint and keep the water out, was now standing out $\frac{1}{2}$ in. in front of the stone which was previously in front of the pointing. How was it that the modern lime pointing put into old work stood up to the acid attack of the atmosphere and the old stone did not? It was a very curious fact. There were examples of Roman pointing at Richborough 1,700 years old, and the pointing was nearly as perfect as the day it was put in. What was the reason for that? Was it the silicates and colloids formed in the pointing or what was it? That might be a line of enquiry which would produce some suggestion as to further attempts that might be made to arrive at a solution of the problem. When he saw Dr. Laurie, a few weeks ago, he said to him: "With regard to your new solution, which is a solution of pure resin dissolved in toluol and certain other additional substances, we do find that it firms up the stone under the most drastic conditions; when flicked on with a camel-hair brush. I receive reports from my

staff that stone the face of which would have been destroyed by a touch has been firmed up and can now be tried with the nail of the finger and is quite firm. My staff tell me it is most hopeful." Dr. Laurie replied: "I wish I could believe that their view was correct. I want to know how long the effect will remain." He said: "Therefore, you do not think that this solution, which is getting us better results than we have ever had, will necessarily be permanent?" and Dr. Laurie replied in the negative. He then asked: "Would you, therefore, consider whether it is possible to produce a clear, colourless flux on the surface of stone which on the application of heat would not alter its colour but would seize the whole surface of the stone? Would you investigate that problem?" It was of course, a problem for the physicist and the chemist, but it might be that advance would take place on those lines, and he had arrived at the following position. He postulated that the whole great wall surfaces of buildings could not be preserved by the application of any special solutions, and that it was necessary to concentrate on the carved, moulded, and other specially worked surfaces. Therefore, he believed that any method which would give a measure of stability to those portions of the building would be invaluable, and the problem ought not to be considered from the point of view of the tremendous expense of applying some system to a whole vast structure, but should be considered from the point of view of applying some system to the moulded and specially worked surfaces only, which had such great interest for the architect, the archaeologist and the artist.

MR J ALLEN HOWE, OBE. (Assistant Director, Geological Survey of Great Britain), said he thought it was no use trying to get solutions of any kind into old rotted stones situated in a building, because it was impossible to get them in far enough. Not a single process had yet been devised for doing that, and it was not likely that one would be found; its practical application was opposed by all the laws of Physics. It might be done if the liquid used were very carefully and continuously soaked in by poulticing, as had been suggested by Prof. Laurie, but this was not economically possible on an extensive scale. That was the definite conclusion he had come to after studying cases of decayed stone in very many buildings not only in this country but abroad for a good many years. The problem of preserving the stones of new buildings might not be so interesting as the problem of preserving them in old buildings, but it was probably quite as important, and certainly not so difficult. Buildings were now being put up of Portland stone and other materials, and they would have to be dealt with by the Office of Works in the future. It must be remembered that fashions altered; a little while ago all the decayed stones were pulled out and new ones put

in, more or less like the originals, and everyone was quite satisfied, but people to-day did not like this. It seemed to him an insoluble problem because we could not afford the cost demanded by the prevalent fashion in taste. With regard to the author's remarks about the difference between Bath and Portland stone and the reason why they did not behave in quite the same way on weathering, he thought the reason was quite clear. The internal structure of the two stones was very different, and he thought the essential difference between them was that in Portland stone there was very much greater agreement in texture and so on between the ooliths and the matrix in which they were situated. That was really the key to the difference between them. With regard to the question of face bedding, a great many stones were found placed in that way, but he thought perhaps the author was a little unfair to Portland stone, if he included it in his strictures. He thought all architects and builders would agree with him. If one looked at the piers of the railings round the Natural History Museum, they showed what bedding in this stone really was. Of course, in some cases it showed true bedding planes, but very often it was really a false bedding, and that could be seen beautifully. It did not hurt the stone at all, because the cohesion was so uniform that it did not matter which way the stone was laid. He was very grateful to the author for putting the case regarding preservatives so clearly, and what the author had said was very much in accordance with what he himself felt about the matter.

DR J J FOX, OBE, FIC (Government Laboratories), said he was very gratified to find that the author had brought together all the information that was scattered about on the subject of the preservation of stone. There were two ways of treating stone with a solution: one was to fill up the pores of the stone and so render the whole impervious, and the second was merely to coat the granules. Personally he had a natural aversion from filling in an old monument: he would rather let it alone and do nothing to it. Sometimes, however, it became necessary to do something, as, for instance, when it was desired to keep an inscription in place. In that case something might be done with a solution in one of the two ways he had mentioned. The information available on the whole subject was rather deficient. In the 1861 Reports on the Houses of Parliament, it would be found that a recommendation was made that a small sum of money should be spent on testing some of the solutions proposed, for it was considered that there was no way of deciding the value of them except by the lapse of time. If the recommendation had been adopted, there would now be available a good deal of information on some of the solutions which were claimed to be preservatives.

There was one point in connection with soot that ought to be known, namely, the destructive effect of the ammonium sulphate contained therein. If a piece of Portland stone was dipped into a very weak solution of ammonium sulphate and the solution was then washed off, a permanent mark was left and calcium sulphate would be found. The action of ammonium sulphate in the soot was entirely different from that of sulphuric acid, but it was an effect that could not be ignored. There was also a point in connection with treating stone with natural gums, linseed oil or resin, which ought to be known rather more widely than it was at the present time. It had been found that, if limestone was treated with some of the resin acids, the stone was actually disintegrated to form calcium resmates. Therefore, although the particles of stone might be held on by being treated with solution and the treatment might be effective for several years, ultimately it would fail. Similar remarks applied to linseed and fatty acids. He deprecated the use of soaps or fatty acids made from any oil like linseed oil; they were unsaturated and chemically very active substances. They were used, however, and if they had to be used at all he would recommend the use of a pure calcium stearate. He had studied the whole subject very carefully and he did not know of anything of universal application. He thought each case must be treated individually and it was frequently best to leave it alone. There were cases in which some good might be done, but he thought they were very limited in number. He believed the baryta treatment would be a failure in most cases.

Mr. A. R. POWIS (Secretary of the Society for the Preservation of Ancient Buildings) said that, in passing through a doorway under an arch where the stones above one's head were crumbling by decay, it was very often noticed that those which came in contact with the shoulder as one passed through were perfectly sound and the moulding was not at all decayed. He imagined that might possibly be due to some grease or other substance from the human beings passing by and rubbing their shoulders against the stone, or possibly the simple removal of dirt collecting on the surface was sufficient to prevent decay for a long time. In the case of an altar slab with a canopy over it, it was sometimes found that the edges of the altar slab, which were touched by the hand, were perfectly sound, whereas the canopy was inclined to decay and fall in dust. The reason for that might be that the canopy was never dusted or kept clean, or it might have something to do with ventilation. He would like to know more about the cause of the difference. The second point he wished to mention, to which he did not think the author attached sufficient importance, was the use of limewash. He

thought it was the invariable custom in mediæval times to limewash buildings. That custom died out during the last century. Buildings that were not used, such as ruined abbeys or castles, had never been re-limewashed since they fell into decay. But where the practice of limewashing had been carried out continually, buildings being limewashed once in fifty years or even more frequently, such as cottages and the lesser farm houses in country districts, the stone work was found to be perfect. Mr. Heaton implied that when a building was limewashed the quality of the stone was lost. It was true that the chisel marks were not seen so clearly, but on approaching a building that had been limewashed one would never take it for any other than a stone building—the stone was quite clear through the limewash. The surface might not have the same beautiful qualities of stone work that was left unlimed, but it had other qualities which were equally beautiful. From his experience of preservatives for stone, he thought limewash was the most certain. It was a preservative that was well understood and it had been used for many generations and was not by any means in the experimental stage. With reference to the author's remark that limewash was apt to be washed away by rain on the surface of a building, by looking at the old cottages and farm buildings where the practice of limewashing had been continued, and where the limewash had been properly applied, it would be found that that was not the case.

MR. GEORGE HUBBARD, F.R.I.B.A., F.S.A., said there was one question he would like to ask the author. In the case of driving rain, of course the rain would penetrate stone, and when frost occurred he presumed that that moisture would freeze, and that the process of freezing and expansion of the moisture would destroy the surface of the stone. In a general way, one would suppose that the denser the stone the more permanent it was, but the denser the stone the less space there was for that expansion of the water when it froze. From the point of view of freezing alone, would not a stone which was loosely composed be able to weather better than one which was very closely composed?

MR. ALAN E. MUNBY, F.R.I.B.A., said that architects were interested in the problem of the preservation of stone, and had been attempting to find a solution, with the very great help of Mr. Howe, not in connection with preservatives, but in making weathering tests upon the stones themselves. Mr. Howe had not said what his Department had done in that connection, and the report on the subject was not yet published. He might say, however, that certain common building stones had been under test for about ten years, and very interesting results had been obtained which established to some extent the order in which the common building stones

might be regarded as weatherers in London. There was only one point he wished to raise, namely, the possibility of getting into the stone a solution of silica. He had always felt that detriment was caused to stone by treating it with re-acting chemical solutions, but if the solution of pure silica was used, five per cent. in water, would it be possible to get that solution into the stone, to a greater depth than was usually the case, by attempting to dry the stone by piercing it to some depth in certain places with ventilation holes? That method of drying stone by ventilation had been used quite successfully by M. Knappen, but there was no necessity to use a tube such as was employed. If holes were bored in the stone a distance of about a yard apart, that would produce a current of air which would withdraw the moisture from the interior of the stone, and that would surely help the solution of silica to find its way further into the stone than it would do in the ordinary way. He thought that was a point that might well be investigated. He wished to conclude by thanking the author very much for his most interesting paper, which crystallised the whole matter, and brought all the information together in a way that could not fail to be of very great service to those interested in the subject.

MR F W TROUP, F.R.I.B.A., said that as an architect he had very often tried to avoid using stone and to use bricks instead! One point had occurred to him which hardly bore on the question of old buildings, and that was in connection with the quarries. In the larger quarries there was probably no difficulty in obtaining men who were really able to deal with the stone properly, and to reject the bad stone, the stone that could not be used, but there were small quarries all over the country and latterly they had been more or less neglected. When an architect came along and wanted to use a local stone, it was no use his ordering it to be cut out of the quarry if the old quarry men had gone. A man could not become a quarry man by simply joining a Trade Union; he had to be born and bred to it: and that was a great difficulty which architects had in attempting to use stone in different parts of the country. They had no difficulty if they were within reach, say, of the Bath stone quarries or the Portland stone quarries, but in many cases he thought it was rather hopeless to insist upon using the stone from the local quarries. With reference to preservatives, he had used one in the case of Bath stone in London about thirty years ago, but he had only seen the building for five or six years after the preservative had been used, and, therefore, did not know what the result was now. In the case of Bath stone, however, it seemed to him it was very difficult to judge of the result of a preservative, as the stone varied so much in quality. Bath stone that was very carefully selected was sometimes nearly

as good as Portland stone, but 50 per cent. had to be rejected in order to obtain that quality, and, therefore, a test of the kind to which he had referred did not give a very conclusive result.

MR. LAURENCE A. TURNER, speaking from the point of view of the stone carver, said that after stone had been masoned and put on a building, it probably stayed there for a year or more before it was worked by the carver, with the result that when the carver began his work he went away the hard face of the stone formed by the quarry water and it did not come again. He was rather surprised that the author did not mention quarry water in the paper, as it was one of the most essential things for protecting the stone. Only that day he had noticed half-a-dozen masons trying to make a certain building in Holborn look like a new building: the face of the Portland stone had been made so hard by the quarry water that they could not get it off, and they could be seen chopping and hammering it in order to break that glassy surface. It was a most distressing sight. There was one other point he wished to mention. During the war he had had the duty of spending many hours in St Paul's Cathedral and he rather doubted whether the dirt on the face of the building was detrimental to the stone. He thought that where Portland stone appeared white was where it had decayed, and where it was black and dirty it had not decayed. If one were on the roof and there happened to be a shower of rain, the first water that came down over the roof and into the gutters was like milk, due to the face of the Portland stone being washed off. Strong evidence that a single coat of paint was an excellent preservative for stone was provided by many tombstones he had seen which had been thus treated. He remembered one particularly, dated 1678, in Beccles churchyard. The inscription had had a single coat of paint put on it and although the face of the stone was worn away the inscription stood out quite clearly. He thought that many coats of paint were not good, but if one thin coat of oil was applied to the stone it soaked into the stone and would give it a hundred years' extra life.

MR NOEL HEATON, in reply, expressed his thanks to those who had taken part in the discussion and said that many of the points that had been raised would be of extreme practical value to all those interested in the subject, and especially to himself. He agreed with most of the Chairman's remarks and did not think his opinions were at variance with those of the Chairman except that variance which was essential to progress. With regard to vegetation, for instance, they were really completely in accord. He did not in the least wish to convey that the presence of lichens on the stone was not a contributory cause of decay to some extent, but he did maintain that under

certain circumstances that decay was more than outbalanced by the advantages the lichens gave in the way of adding beauty to the stone and to a certain extent giving the stone resistance to certain forms of corrosion.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr Heaton for his interesting paper, and the meeting then terminated

PROFESSOR CECIL H. DESCH, D Sc., Ph D., F.I.C., writes:—

After reading Mr Heaton's interesting account of the state of knowledge in regard to the preservation of stone, I find myself in almost complete agreement with him. I would emphasise the statement that nothing is to be expected from secret processes. It is quite certain that no secret information exists as to preservatives of greater value than those of which the chemical character is quite well-known. My own experience is that the silicofluorides (this name is to be preferred to Fluosilicates, as having been adopted by the Chemical Society as a scientific name) afford better preservation than any other materials. Treatment with wax has its advantages and may be used with care, but the actual hardening of the surface which is brought about by the chemical reaction between the silicofluorides and calcium carbonate causes a true hardening of the stone as well as a reduction of porosity. When, however, the salts are applied in an unintelligent manner there is danger that a hard, impervious layer may be formed at the surface, which may scale when water gains access to the interior of the stone through joints. The object should be, not to render the surface completely impervious, but to reduce the porosity so far that destructive agents do not enter the stone, whilst leaving opportunity for slow evaporation of contained water. There is no doubt that more careful treatment of the stone in quarrying, and in bedding correctly, would save much of the present trouble. A most striking instance is that of Lincoln Cathedral, where the stone, carefully chosen from a good quarry, has preserved its texture most perfectly, so that the fine mason's marks are still quite clear. The only change in the stone in this case has been a gradual solution and re-deposition of calcium carbonate which results in closing the pores. Unfortunately in modern town atmospheres this action is completely prevented by the presence of sulphur compounds, and chemical treatment is, therefore, called for. I am thus in agreement with Mr Heaton's conclusions with the exception of No. 4, for which I would substitute a recommendation of careful treatment with silicofluorides.

MR. H. O. WELLS, Director of Building Research, Scientific and Industrial Research Department, writes:—

I congratulate the author on his industry in putting together so many facts up to the present not connected, and on his careful analysis of these facts. I am pleased to see that his conclusions agree with those I formed when initiating the research work which has been carried out by this Board during the last year, i.e., that all the work previously had merely resulted in more or less guarded confessions of failure by all disinterested investigators. The only exception was that the use of silicofluorides had been found effective in many instances. It seemed, therefore, the only line of advance to investigate the use of silicofluorides. Dr. Desch, of Sheffield, very kindly allowed us to be associated with the work he had started some years ago; one investigator working under him has now worked out the proper salt to use, and the proper treatment with that salt for most of the best known building stones in the kingdom. The results will be published as soon as possible.

I agree with the author in criticising the careless treatment of stone by many architects. There are bad examples in London and through the country of good stones used without regard either to sound tradition or to the discoveries of modern science. For instance, in the front of one well-known London hospital the ends of iron ornamental railings have been embedded in stone piers and sulphur run round them. The result is that the stone piers have been wrecked. In a new public building in the North of England, a local sand containing oil was used in the mortar; the result is an oily stain spreading up into the stone from the mortar joints. Sound tradition would prohibit sand altogether. There has also been neglect of sound tradition in the building of stone war memorials up and down the country. I know of two in one country town; one in the market place, where a thin facing of limestone has been used as a retaining wall right up against damp sand; the result being a pattern of hideous blotches of damp on the surface; while worse results will probably follow as time goes on. The other memorial, in the churchyard, has been to all appearances purposely designed to lead rain water falling on the upper part of the stone right across the inscribed panels. The inscription will inevitably be torn out by the mere mechanical action of the rain within a few years.

OBITUARY.

RALPH BROCKLEBANK, J.P., D.L.—Mr. Ralph Brocklebank, of Haughton Hall, Nantwich, died on the 19th inst. at the age of 81. He was born at Childwill Hall, Liverpool, and for many years was a partner in the well-known Brocklebank shipping firm. He was also Chairman of the locomotive committee of the London and North Western Railway.

His estate at Tarporley was regarded as one of the model estates of Cheshire

Mr. Brooklebank was elected a Fellow of the Royal Society of Arts in 1918. His name appeared in the recently published first list of contributors to the Fund for purchasing the Society's House, as a donor of £100.

THE MINERAL RESOURCES OF CZECHO-SLOVAKIA.

The deposits of iron ore in the Slovak country are very extensive. Two general regions may be distinguished, the Spis district and the district of the north-eastern Carpathians.

In the Spis district about 89 square kilometres of land are held by mining companies, an area equal to about 22,000 acres. In 1917 this territory produced 1,215,500 metric tons (metric ton=2,204 pounds) of iron ore; in 1912, two years before the war, the yield was considerably larger - 1,529,430 metric tons. The ore contains from 35 to 46 per cent of pure iron. According to the most careful estimates of geologists, the mines of the Spis district still contain about 26,143,500 metric tons of ore, easily accessible, and an additional quantity of about 47,680,000 metric tons, also available but not so easily mined.

The second district, that of the north-east Carpathians, is comparatively poor in iron ore, though mining operations are carried on there. This region includes all those workings in the counties of Saris, Zemplin, Uzhorod, Bereg, Ugocsa, and Marmaros. In 1912 the production was 4,000 metric tons of the mineral. The total capacity of the mines in this district is estimated at about 960,000 metric tons.

Hitherto, according to a report by the United States Assistant Trade Commissioner at Prague, the mines of Slovakia have been owned and exploited wholly by foreign capital. Slovak labour was utilised in the actual working of the mining, but the great rewards went out of the country. At first it was German capital which operated the mines of the Carpathians. More recently this has given place to Hungarian capital. At present the iron mines and some of the others are almost entirely in the hands of three companies, which have been combined to form one great trust.

The first of these was the Rimamuran-Salgotarjan Iron Co. ('Rimamurany-Salgotarjani vasmu r t.'), of Budapest. The second was the Hornad Valley Hungarian Iron Co. ('Hornadvölgyi magyar vasipar r t.'), also of Budapest. The third, called the 'Union' Co., had its main offices in Vienna as well as in Budapest. The holdings of the two last-named companies have been long since acquired by the first, so that all three together now form a single enterprise.

This trust owns large iron mines at Slovinky

and at Horní Medzév. The great lime and magnesite quarries, together with two limekilns, also belong to it. It owns blast furnaces at Likier and Hust and steel works at Salgotarjan and Ozd, outside of Slovakia. It employs altogether about 7,000 workmen and its machinery represents a total of 15,000 horse-power.

From 1915 to 1916, the forests on the lands belonging to the combine were extensively exploited. About 50,000 cubic metres of lumber were sawn. In that same year 320,000 metric tons of iron ore were taken out of its mines, 120,000 metric tons of limestone, and 5,100 metric tons of magnesite, the last named solely for the company's own uses. Previous to the war, its blast furnaces worked day and night from one end of the year to the other. The blast furnaces of Likier and Hust turned out about 150,000 metric tons of pig iron per year.

The Hornad Valley Co., now a part of the trust, produced, in 1914, about 113,000 metric tons of iron ore, 74,000 metric tons of pig iron, 130,000 metric tons of steel, 30,000 metric tons of forged and 70,000 metric tons of rolled goods, as well as 2,000 metric tons of brass. It worked 5 iron mines, from some of which copper was also taken, and 15 other concessions. Its greatest foundries are at Krompachy, on the line of the Kosice-Bohumin Railway.

Slovakia is less favoured in the matter of coal deposits. Its total coal resources have been estimated at about 1,717,700,000 metric tons. These deposits have scarcely been touched, inasmuch as coal mining in Slovakia only began about 10 years ago. The capital is entirely non-Slovak. The largest coal mines are at Handlova, in the county of Nitra. They have been in operation since 1910. The coal is of excellent quality. The future of these mines seems a bright one. The mines at Jedlove Kostolany, near Zlate Moravce, are smaller and the workings are in bad condition. The machinery needs thorough overhauling. There are also small but well-worked mines in Rapovce, near Lucenec.

The oil resources of Slovakia are undoubtedly one of the great assets of the Czecho-Slovak State. There are three basins, situated far apart, where oil is either flowing or is being prospected for.

The first of the districts is that of Gbely, in the Morava basin, where the Austro-Hungarian Government began prospecting in 1912, and where about two tank cars of naphtha were extracted daily, yielding a very excellent quality of machine oil. This same oil is now being used for the Czecho-Slovak State railways for lubricating purposes.

The second district is at Turzovka, in the county of Trencin. It has been recently reported that rich new oil wells have been discovered in this district. There seems to be a connection between these wells and those of Galicia. The prospecting in this district, interrupted by the war, is now being resumed with good results.

The third region is in the northern part of the county of Zemplin. English capital, as well as Hungarian, has been interested here. Prospecting has gone on in this part of the country almost up to the frontier of Galicia.

In addition to iron, coal, and, oil, there are other minerals of considerable importance in manufacturing and the arts: Calciferous rocks for making lime and cement, sand for making glass, porcelain earth and kaolin, common salt, precious stones, opals, antimony, copper, manganese, cobalt, nickel, cinnabar, and pyrite. The antimony mines are especially valuable. There are two deposits being worked, one in the county of Bratislava, near Pernek and Stupava, and the other in the county of Spis, near Smolnik and Gelnica.

The near future will probably see a more extensive exploitation of the mineral resources of Slovakia. It should also be remembered that, although there is not a very large supply of native coal to furnish motive power for industry, there are numerous excellent hydraulic sites along the streams flowing down from the Carpathians. The possibilities of water-power development, scarcely experimented with as yet, are unquestionably great in this part of Czecho-Slovakia.

The important deposits of magnesite in Slovakia, which from 1910 to 1913 formed the largest export from the former Austro-Hungarian Empire to the United States, are calculated to constitute about one-tenth of the world's total supply

THE PRODUCTION OF WOOD OIL IN CHINA.

One of the most important native products of China is wood oil. This oil is called nut oil in the United States, because it is expressed from a nut, but in China it is known as wood oil because it is chiefly used on wood. The demand for Chinese wood oil increased in a remarkable way during the war owing to the general increase of war industries in the Allied countries. The export of this commodity from Hankow has gone forward by leaps and bounds until it now stands second in rank of all commodities exported from this centre.

According to a report by the U.S. Vice-Consul at Hankow, wood oil is obtained from two varieties of *Aleurites*, a small genus of the spurge family. There are, Wilson states, *Aleurites montana* and *Aleurites fordii*. The former, or "mu yu," as the natives call it, is largely confined to southern China, while the latter, known as "tung yu shu," flourishes best in central and western China, where it is widely distributed. The "tung yu shu" is by far the more important of the two species and furnishes the major part of the wood oil which is exported from China.

Both species are hardy trees and grow luxuriantly in a hilly country up to an altitude

of 2,500 feet. They seem to thrive in poor soil and are able to withstand long periods of drought; they are found as far north as 24° latitude, but in such a severe climate fail to bear fruit on account of the cold. A full-grown tree is about 20 feet in height and the trunk measures 6 to 12 inches in diameter. The "tung yu shu" tree is deciduous and sheds its leaves in October and November. It is low spreading, and in the spring produces a great profusion of white blossoms and flowers, the petals of which are sprinkled with pink and yellow. The fruit of the tree is about the size of a large walnut, in shape not unlike a persimmon with a smooth exterior and contains from 3 to 5 seeds. When ripe the husk bursts open and the seeds or nuts fall to the ground.

The oil is generally bought up by dealers in cities or interior market places and held for speculation. It is with these dealers, or in some cases the mill owner, that the comprador of a foreign firm has to deal. When a shipment of wood oil has been purchased by the comprador it is placed on board a Chinese junk for transportation to Hankow. Each junk holds from 300 to 700 baskets, which are lined with layers of varnished paper. En route the cargo is liable to taxation in various forms by the numerous military officers through whose territory it passes.

Over 60 per cent of the wood oil entering Hankow comes from Szechwan or Kweichow and has to pass through the Yangtze gorges, where many cargo boats are wrecked. Since the foreign manager in Hankow buys his wood oil from the comprador he prefers that the comprador take these risks, and consequently only pays for pure oil laid down in his godown at Hankow. Insurance rates on junks making the trip from Szechwan to Hankow are prohibitive. Some companies send small lighters into Hunan in order to tow cargo boats loaded with wood oil purchased in that Province. Others buy their oil from Chinese dealers in Hankow who have bought cargo in the interior.

Upon arrival at Hankow the wood oil is transported from the boat to the godown by coolies. In the godown the wood oil is usually allowed to settle for some time in the sun before the baskets are emptied. The clear oil is weighed and strained into a pump which forces it into huge storage tanks. In the winter, when the oil solidifies, the basket is stripped off and the débris is removed by cutting the bottom of the cake off. After this it is necessary to heat the mass in order to allow precipitation to take place.

Each godown has one or several huge storage tanks, the capacity of which varies from 30 to 1,000 tons. The bottoms of these tanks are conical, resting on a concrete foundation. They are tapped by faucets or cocks placed at various heights on the tank. All the oil drawn off through the top faucet is sure to be pure. The impure oil and sediment are drawn off

through the lower cocks. The comprador of the firm is paid only for the pure wood oil. The débris and impure oil are weighed and sold for his account to local Chinese merchants, who in turn sell it to Chinese boatmen. A barrel factory is usually operated in connection with a wood-oil godown. The hoops and barrel staves are generally imported and set up in the factory. These barrels are usually made of oak and are said to be able to withstand four or five round trips between China and foreign countries. It is into these barrels that the refined product is poured ready for shipment. A barrel of wood oil weighs 450 pounds.

Wood oil is composed principally of the glycerides of oleic and clæomargaric acids and quickly becomes jellified when it is allowed to stand. Each firm has its own secret test for determining the purity of wood oil. When heated to 500° F. for a short time wood oil solidifies to a jellylike mass. This property forms the basis of the heat test for Chinese wood oil, which is very useful in determining its purity. On account of its high price it is often adulterated by the Chinese dealers. Many foreigners, inexperienced in the ways of Chinese sellers, have had sad experiences in connection with wood-oil purchases. Adulteration generally takes place when the market value is up, and soya bean, peanut, sesamum seed, and cotton seed oils are the usual adulterants.

The specification of the New York Produce Exchange in regard to wood oil is as follows:

Sec. 25. Pure China wood oil shall answer the accepted chemical requirements

Sec. 26. Commercially prime China wood oil shall be pale in colour (according to season's production), merchantably free from foets, dirt, and moisture. The total impurities shall not exceed 1 per cent.; but, unless otherwise provided for, impurities not plainly adulterations, up to 5 per cent. shall not justify rejection, but allowance shall be made by sellers for such impurities in excess of 1 per cent. The oil shall stand the heat test, herewith subjoined:

Heat or coagulation test for China wood oil.—

One hundred grammes of the oil is heated in an open metal pan, 6 inches in diameter, as rapidly as possible, to a temperature of 540° F. The time required to heat the oil from room temperature to 540° should be, as nearly as possible, the same each time, four minutes being usually sufficient with gas burners. Hold the oil at or as near to 540° as possible, stirring until it begins to solidify. Note the time required after the oil reaches 540° and until it begins to solidify. This should not exceed seven and one-half minutes for any commercially prime wood oil. When the oil has solidified in the pan, turn it out while still hot and cut with a knife. Commercially prime wood oil gives a product that is pale, firm and cuts under the knife like dry bread, not sticking. If the oil requires more than seven and one-half minutes after reaching

540° until beginning to solidify, or if the product is dark, soft or sticky, the oil may be rejected.

Other heat tests used by local business men are Bacon's, Browne's, and the Pratt and Lambert tests.

The heat tests, together with the determination of the specific gravity, iodine number, saponification number, refractive index, etc., usually determine the purity of Chinese wood oil.

China wood oil is largely used as a substitute for linseed oil, varnish, linoleum, and paint, because of its rapid drying properties. The Chinese have many uses for wood oil, the most important of which is as a preservative for the thousands of boats that ply on China's inland waterways. The Chinese junkman never paints his boat but coats it with the cruder grades of wood oil; this not only gives the woodwork a bright lustre but acts as a preservative. The residue of the wood oil nut after the oil has been extracted is sometimes burned to a soot, which is mixed with oil to make a paste for caulking boats. Another combination used by the Chinese boatman for caulking purposes is a mixture of the oil with lime and bamboo shavings. Wood oil is also used as a dressing for leather, as varnish for furniture, in soap making, and in making lacquer.

The native combines certain mineral substances with wood oil, and by cooking the mixture produces a substance known as "kwangyu," which is used by the Chinese in waterproofing the paper employed in the manufacture of Chinese umbrellas. The oil is also used by the natives for waterproofing cloth shoes, silk, pongees, and other materials. By means of this substitute the Chinese have managed in a remarkable way to get along without the use of rubber. The best grades of Chinese ink are obtained by burning the oil or husks from wood oil nuts. The residue of the nut, like the oil, is poisonous and is used chiefly as a fertiliser.

The price of wood oil, like any other commodity, determines to a large extent the quantity exported in any one year. The demand from foreign countries continues to increase. The quantity available for export depends upon political conditions in the interior, and these in turn react on local prices. It often happens that certain producing regions are practically cut off by the presence of bandits in those particular localities.

The total quantity of wood oil exported from China to foreign countries during the years 1912-1920 was as follows:—

Years.	Pounds.	Years.	Pounds.
1912.....	77,708,400	1916.....	68,689,600
1913.....	61,819,600	1917.....	53,514,800
1914.....	58,515,600	1918.....	65,180,000
1915.....	41,379,200	1919.....	81,794,000
		1920.....	72,095,600

It is understood that successful attempts have been made to grow the wood oil nut in some parts of the United States. In China the farmer receives no help of any kind from the Government. To further the continued growth of this promising industry in China, adds the United States Vice-Consul, Government aid is urgently needed. In his opinion nurseries should be established where tree selection can be carried out for the benefit of the grower, and farmers should be taught a uniform method of picking the fruit, upon which depends to a large extent the amount of oil obtained from the nut. The present crude methods of crushing the nut result in a great amount of waste. If the Chinese could be induced to instal modern machinery in place of the native presses now in use, the Vice-Consul thinks it would mean a saving of 10 per cent. or more

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

JANUARY 18.—JULIAN S. HUXLEY, M.A., Fellow of New College, Oxford, "The Control of Sex in Animals."

JANUARY 25.—HOWARD MAURICE EDMUNDS, "Photo-Sculpture."

FEBRUARY 1.—ARTHUR WILCOCK, "Surface Printing by Rollers in the Cotton Industry."

FEBRUARY 8.—EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "Some Solved and Unsolved Problems in Gas Works Chemistry." SIR ARTHUR DUCKHAM, K.C.B., M.Inst.C.E., in the chair.

FEBRUARY 15.—CLOUDESLEY BRERETON, M.A., Divisional Inspector to the London County Council (Modern Languages), "The Necessity of Speech Training, and the Need of a National Conservatoire."

FEBRUARY 22.—ALEXANDER SCOTT, Sc.D., D.Sc., M.A., F.R.S., "The Restoration and Preservation of Objects at the British Museum."

MARCH 1.—EMANUEL MOOR.

MARCH 8.—W. A. APPLETON, C.B.E., Secretary to the General Federation of Trade Unions, "The Proper Functions of Trade Unions." JOHN MURRAY, M.P., in the chair.

MARCH 15.—OSWALD T. FALK, "Certain Aspects of the Problem of Exchange Stabilisation." SIR ROBERT M. KINDERSLEY, K.B.E., in the chair.

MARCH 22.—PRINCIPAL A. P. LAURIE, M.A., D.Sc., F.R.S.E., "Permanency of Oil Colours."

MARCH 29.—SIR THOMAS OLIVER, LL.D., D.Sc., M.D., F.R.C.P., "Alcohol in Relation to Industrial Hygiene." (Shaw Lecture.)

Dates to be hereafter announced:—

LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry."

GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

PROFESSOR ERNEST R. MATTHEWS, "Sea Encroachment and its Prevention."

PHILIP SCHIDROWITZ, Ph.D., F.C.S., "Recent Developments in India Rubber Manufacture."

MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock.

JANUARY 27.—ALEXANDER L. HOWARD, "The Timbers of India and Burma." THE RIGHT HON. E. S. MONTAGU, M.P., Secretary of State for India, in the chair.

MARCH 24.—PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India."

APRIL 28.—F. G. ROYAL-DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the chair.

MAY 26.—PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow. Magdalene College, Cambridge. (Sir George Birdwood Memorial Lecture.)

Date to be hereafter announced:—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoon, at 4.30 o'clock.

MARCH 7.—MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E., "Tanganyika Territory (formerly German East Africa)."

Date to be hereafter announced.—

LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, G.B.E., K.C.M.G., "Queensland."

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETING.)

Friday afternoon, at 4.30 o'clock.

FEBRUARY 24. — PROFESSOR WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S., "Brown Coals and Lignites: Their Importance to the Empire."

CANTOR LECTURES.

Monday evenings, at 8 o'clock.

C. AINSWORTH MITCHELL, M.A., F.I.C., "Inks." Three Lectures.

Syllabus.

LECTURE I.—JANUARY 23.—Historical Introduction—Nature of Inks—Egyptian and Chinese Inks—Modern Carbon Inks—Sepia—Iron Gall Writing Inks—Methods of Preparation Properties—Iron Tannates.

LECTURE II.—JANUARY 30.—Logwood Inks—Vanadium Inks—Aniline Inks—Coloured Writing Inks—Examination of Writing Inks—Characteristics of Ink in Writing—Copying Inks

LECTURE III.—FEBRUARY 6.—Marking Inks—Printing Inks—Preparation of Lamp Black—Carbon Blacks—Boiled Oils—Typing Ink—Inks for Miscellaneous Purposes—Secret Writing.

ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., late Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington, "The Mechanical Design of Scientific Instruments." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 20.—Design from the point of view of the User and the Manufacturer—Clerk Maxwell's axioms of Instrument Design—Degrees of Freedom and Constraint—The Six Degrees of Freedom of a Rigid Body—Geometric Design.

LECTURE II.—FEBRUARY 27.—The Lower and Higher Pairs—Restraint against Sliding—Restraint against Rotation—Centroids and Axodes—The Design of Profiles.

LECTURE III.—MARCH 6.—The Elastic Nature of all Materials—The Elastic Constants—The Rigidity of Instruments—Manufacture—Models—Interchangeable Manufacture.

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry,

College of Technology, Manchester. "The Constituents of Essential Oils." Three Lectures. March 20, 27, April 3.

COBB LECTURES.

Monday evenings, at 8 o'clock.

F. F. RENWICK, F.I.C., F.C.S., A.C.G.I., "Modern Aspects of Photography." Three Lectures. May 1, 8, 15.

MANN JUVENILE LECTURES.

Wednesday afternoons, January 4 and 11, at 3 o'clock.

WILLIAM REGINALD ORMANDY, D.Sc., "Clay: What it is—Where it comes from—and What can be done with it."

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.

MONDAY, JAN 2. Architectural Association, 34, Bedford Square, W.C., 8 p.m. Mr H. S. Goodhart-Rendel "Classic Architecture in England (1650-1850); Its story and its Teaching" (Geographical Society, 135, New Bond Street, W., 3.30 p.m. (Juvenile Lecture) Miss Ella Sykes, "A Ride on the Roof of the World."

TUESDAY, JAN 3. Royal Institution, Albemarle Street, W. 3 p.m. (Juvenile Lecture) Prof. J. A. Fleming, "Electric Waves and Wireless Telephony." (Lecture III) Automobile Engineers, Chamber of Commerce, Birmingham, 7 p.m. Mr. W. W. Hackett, "Experiments with Weldless Steel Tubing as used in Construction." Photographic Society, 35, Russell Square, W.C., 7 p.m.

WEDNESDAY, JAN 4. Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. (Wireless Section). Lt.-Col. A. G. T. Custus, "High Speed Wireless Telegraphy." Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 3 p.m. (Juvenile Lecture) Miss E. M. B. Warren, "Through the Land of the Maple Leaf."

THURSDAY, JAN 5. Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Wing Commander W. D. Beatty, "Specialised Aircraft." Royal Institution, Albemarle Street, W., 3 p.m. (Juvenile Lecture). Prof. J. A. Fleming, "Electric Waves and Wireless Telephony." (Lecture IV.)

Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. Dr. S. Parker Smith, "Single and Three-Phase Commutator Motors with Shunt and Series Characteristics."

FRIDAY, JAN 6. Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. "The Co-operation of the Engineer and Chemist in the Control of Plants and Processes." (Joint Meeting with the Society of Chemical Industry.)

Geographical Society, 135, New Bond Street, W. 3.30 p.m. The President, "Pictures from Mount Everest."

Chemical Industry, Society of (Manchester Section), Joint Meeting with the Institute of Chemistry, Society of Dyers and Colourists, and Manchester Literary and Philosophical Society) at the Textile Institute, 16, St. Mary's Parsonage, Manchester, 7 p.m. Prof. A. Harden, "Biochemical Method."

SATURDAY, JAN 7. Royal Institution, Albemarle Street, W., 3 p.m. (Juvenile Lecture). Prof. J. A. Fleming, "Electric Waves and Wireless Telegraphy." (Lecture V.)

Journal of the Royal Society of Arts.

No. 3,607

VOL. LXX.

FRIDAY, JANUARY 6, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W C (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 11th, at 3 p.m.
(Juvenile Lecture.) * WILLIAM REGINALD
ORMANDY, D.Sc., F.I.C., "Clay: What it
is—Where it comes from and What can
be done with it."

"OWEN JONES" AND "MULREADY" PRIZES

The Council of the Royal Society of Arts hold a sum of £400, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them by the Committee of that fund in 1876, on condition that the interest thereof be spent in Prizes to "Students of Schools of Art. who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damasks, Chintzes, etc., regulated by the principles laid down by Owen Jones."

The Council offer six Prizes in 1922, for the following subjects:

ARCHITECTURAL DECORATION: Including Stained Glass, Mosaic for Walls and Floors, Plasterwork in relief and incised, Inlaid Marble and Stones, Lettering for Memorials.

WOODWORK AND CABINET WORK: Including Carving in Wood, Ivory and Bone, Inlay, Chairs, Chests, Cabinets.

TEXTILES*: Including Tapestries, Carpets and Rugs, Moquettes, Floor-coverings (*e.g.* Linoleums and Floor-cloths).

Each Prize will consist of the Society's Bronze Medal and a copy of a book or books on Applied Art, of a value not exceeding £2. to be selected by the successful competitor.

In addition to the above prizes, A SPECIAL PRIZE OF TWENTY POUNDS is

* It should be noted that only the classes of Textiles mentioned above are eligible in 1922.

offered, under the Mulready Trust, for the best design (irrespective of class) submitted for competition.

The Council reserve the right of withholding any or all of the Prizes offered, and they will be the sole judges in each individual case of the qualifications of a competitor to receive an award.

The competition is limited to Students of Schools of Art.

Competing designs must be sent, carriage paid, and labelled "Owen Jones Prize Competition" on the outside, to

THE DIRECTOR AND SECRETARY,

Victoria and Albert Museum,

South Kensington, S.W. 7.

between June 12th and June 17th, 1922. They may be delivered by hand on any of the three days ending June 17th.

The sender must also notify the Secretary of the Royal Society of Arts by post that the design has been sent in, and must enclose stamps or P.O.O. for the return carriage.

The awards will be made by the Council of the Royal Society of Arts on the recommendation of Judges appointed by them.

Arrangements will be made, if possible, for the public Exhibition of the competing designs in the Victoria and Albert Museum, South Kensington, as in previous years.

All possible care will be taken of the designs, but the Council accept no responsibility for injury or loss.

CASES FOR JOURNALS.

Cases for keeping the current numbers of the *Journal* are now obtainable. They are in red buckram, and will hold the issues for a complete year. They may be obtained post free, for 7s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES SECTION.

TUESDAY, DECEMBER 6th, 1921.

HIS GRACE THE DUKE OF DEVONSHIRE, K.G., G.C.M.G., G.C.V.O., LL.D., Governor-General of Canada, 1916-1921, in the chair.

THE CHAIRMAN said his task that evening was a very simple and pleasant one, namely, to introduce Mr. Wade, the Agent-General for British Columbia, who was to deliver a lecture on the subject of that very great and beautiful country. He did not think he should be giving any wrong advice if he advised all who had not yet seen the country to take an opportunity of doing so. It was a country which personally he had the greatest sympathy, regard and affection for, not merely on account of its wonderful natural assets and its great scenery but for the splendid character and robustness of its inhabitants. In the earlier stages of the war, in 1914, he believed the great province of British Columbia suffered to a large extent. There was no waiting there—all classes of the population at once flocked to the colours and the record of service and work done by that Province was one which at all times would be memorable in its history. He knew that those present were most anxious to hear the lecture and he therefore had the greatest pleasure in introducing Mr. Wade.

BRITISH COLUMBIA: THE AWAKENING OF THE PACIFIC.

BY FREDERICK COATE WADE, B.A., K.C.,
Agent-General for British Columbia

Columbus did not know that he had discovered America. When the cannon shot from the *Pinta* on the night of October 12th, 1492, proclaimed land in sight, he was convinced that he had at last reached the islands on the coast of India. Hence, St. Salvador and the rest of the Islands became the West Indies. When on his fourth voyage, ten years afterwards, he reached Darien (now Panama) he believed he was on the Continent of Asia. The aboriginals of America were, therefore, called Indians. Strange to say, he thought he could reach the East Indies through the Isthmus of Darien (which we now do) and tried to do so, but without success. He died quite ignorant of the responsibility he had incurred in discovering America.

Unless Balboa had been hopelessly in debt, it is impossible to tell when the Pacific Ocean would have been found out. Having

failed as a planter in Haiti, to escape his creditors he hid in an empty cask, and became part of a ship's cargo on the way to the mainland of South America. On September 25th, 1513, from the summit of a mountain at a point opposite the Gulf of Miguel he beheld the Mar del Sur (the Southern Sea), seven years later to be visited by Magellan and named the Pacific Sea. On September 28th Balboa took formal possession of the Southern Sea, by marching into the waters and claiming both seas and land in the name of the King and Queen of Castile. The people of the Pacific are deeply indebted to the creditors of Balboa, who four hundred years ago chased him into a hollow cask and started him on his momentous mission.

Balboa had heard of the silver mines of Peru and of her civilisation. Columbus probably had found out a good deal at Darien. No wonder that, like Alice, they were all anxious to get behind the looking-glass, and to some extent Balboa and Magellan succeeded.

From the time of Columbus up to the memorable voyage of Captain Cook, and even later, the attempt to discover the Straits of Anian or the North West passage through the continental mass of America to India led to a series of voyages—Spanish, Portuguese, Russian, British, French and American—full of adventure, hardship and romantic daring and worthy of the best traditions of the human race. On the Atlantic side Cabot, Cortereal, Frobisher, Baffin, Hudson, on the Pacific, Cortes, Pizarro, Maldonado, Mono de Guzman, Juan de Fuca, Dechenev, Baring, Tchirikoff, Drake, Cook and Vancouver, Kendrick and Gray, nosed their ships' prows along the shores of both oceans looking for the mythical Straits of Anian, the supposed short and direct route through the continent to and from India. It is interesting to know that in one of these voyages Frobisher named Greenland West England and the last cliff he sighted on leaving, he called "Charing Cross." There is a point on the east side of Newfoundland I believe, called Piccadilly, an irreverent Cockney sailor's corruption of Pic St. Denis.

The passage was never found. Someone has said that if no Sabbath had been ordained, it would be necessary to create one. The solution came with the building of the Panama Canal. It is interesting to note that the building of a canal across

the Isthmus had been urged on the attention of the King of Spain by Galvao, a Portuguese navigator in 1520, but for political reasons the project was suppressed and the death penalty attached to any attempt to re-open the matter.

From 1608 to 1768 the north-west coasts of North America were entirely neglected. In 1763 Canada was added to Great Britain. But the distance by Cape Horn from Liverpool to the coast which is now British Columbia was 14,558 miles, as against 2,456 miles to Halifax on the Atlantic. It was this difference in distance which caused the lop-sided development of the American Continent, the early occupation of the Atlantic Coast as against the retarded settlement of the coasts of the Pacific. Had the Straits of Anian been a fact instead of a myth, or had Antonio Galvao in 1550 succeeded in having a canal built through the Isthmus of Darien to reach the sub-tropical coasts of the Pacific, settlement on the Pacific Coast would have kept pace with that on the Atlantic. Some malicious Westerners say that the charms of the Pacific are so superior to those of the Atlantic Coast that if the race had been an even one, the Atlantic Coast would not have been settled yet.

The cutting of the Panama Canal has reduced the distance from Liverpool to Victoria, British Columbia, from 14,558 miles to 8,512. The distance by land and sea from Vancouver to Liverpool *via* Montreal is about 5,852 miles as against 8,512 miles by the Panama Canal, the all-sea route. The difference between the old all-sea route 'round Cape Horn and the trans-continental and Atlantic route was 8,706 miles. The difference between the all-sea route by the Panama Canal and that *via* Montreal and the Atlantic is only 2,660 miles. The disadvantage in distance by sea as against that over land and sea has been lessened more than two thirds, if it does not approximate to three-fourths. What this means to commerce and civilisation in and around the Pacific can scarcely be conjectured. The discovery of America by Columbus has been described as "the God-like gift to humanity of half a world." The opening of the Panama Canal is the gift of the other half.

It is too soon to make a comparison of freight rates from the Pacific Coast and Central Canada to Europe *via* the Panama Canal with the rates across the Continent

and *via* the Atlantic. Traffic by the new route is only in its inception and rates have not become stabilised. It can be pointed out, however, that the Vancouver route embraces a much larger proportion of water mileage, that it is on the water that the greatest competition exists, and consequently the greatest tendency to shrinkage in rates. As an instance of what water carriage means as against land carriage, take Regina, situated almost the same distance from Halifax, as Halifax is from Liverpool. The shipment of a quarter of wheat from Regina to Liverpool costs, say, 21s., but of this total only 4s. represents water carriage, while 17s. represents land carriage, though the distances in each case are practically the same.

The Great War has produced several new factors which profoundly affect the whole position of the railroad and grain interests in the Dominion :

1. Great increase in the cost of rail haulage.
2. Great expansion of ocean tonnage.
3. The availability of some of this tonnage to provide new services for the west coast of Canada at rates based upon the highly competitive nature of sea transport under peace conditions.

Another important factor to be considered is the revolution in transportation by the introduction of the motor boat with Diesel engines using oil for fuel. It is unquestionably the fact that the Swedish line of motor freighters of the North Star or Johnson line now operating out of Vancouver through the Panama Canal is run at a considerable saving on the cost of steam transportation. Grain is transported to Europe by the cheapest of all kinds of transport (namely, by all water, or almost all water) from the Argentine, Australasia, East Mediterranean, India, etc., and it is no rash prophecy to say that before long the great bulk of the grain of Western Canada will adopt the sea route as well. Indeed, the movement is already in full swing. On February 9th, 1921, the Buenos Aires of the North Star or Johnson line of Stockholm brought the first direct commercial shipment of Canadian wheat (3,200 tons) from Vancouver to London. It was No. 2 Northern Manitoba wheat, and arrived in perfect condition. During the fiscal year ending June 30th, 1921, there were sailings through the Canal from British Columbia to the United Kingdom and Northern

Europe, to the Atlantic and Gulf Coast of the United States, to Mexico, the Mediterranean, Cuba, the East Coast of South America, and Eastern Canada, and of these 20 cargoes, aggregating 138,435 tons, were bound to the United Kingdom and Northern Europe alone.

In considering the extent to which the wheat of Western Canada will be routed to Europe *via* Panama, it is important to remember how much nearer the wheat centres of Western Canada are to the Pacific than to the Atlantic Sea board. The following is a table of distances from some of the principal cities in the great western Provinces, Manitoba, Saskatchewan and Alberta to Vancouver, Montreal and Halifax respectively :—

	Miles from		
	Vancouver.	Montreal.	Halifax.
Brandon ..	1477	1507	2348
Regina ..	1256	1727	2568
Saskatoon ..	1096	1842	2693
Battleford ..	1025	1983	2824
Edmonton ..	770	2167	3003

Brandon in Central Manitoba is 30 miles nearer to Vancouver than to Montreal and 871 miles nearer Vancouver than to Halifax. Regina in Saskatchewan is 471 miles nearer to Vancouver than to Montreal, and 1,312 miles nearer to Vancouver than to Halifax. Edmonton in Alberta is 1,397 miles nearer Vancouver than she is to Montreal and 2,238 miles nearer to Vancouver than to Halifax. It is obvious that the rail haul is much shorter to the Pacific than to either Montreal or the Atlantic from most points in Western Canada. Just as the Great Divide marks the point where the great rivers of the west have their common source and then separate to flow east and west, there is a Great Economic Divide between conditions and distances which will determine how much of the product of Central and Western Canada will be carried east and west respectively. Whether that point is Regina or Moose Jaw remains to be determined.

But there are even other important factors to consider. The great inland water-ways of Canada are available only in the summer months. Montreal is not available as a port after the close of navigation. Vancouver and Prince Rupert and the whole coast line of British Columbia are open throughout the year. Not only are the ports open but there is not a day in the year when the

weather is cold enough to interfere with work.

Another serious factor which alone will force the adoption of the western route for moving a great part of the crop is the danger of freight congestion, and shortage of cars in the east. Last August, when a serious congestion was more than threatened in Montreal, the Winnipeg correspondent of the Vancouver Province said :—

“Exporters here state it is most important that at least 75,000,000 bushels of the export surplus should be got out before the close of navigation, but are pessimistic as to how it is to be done. It is of the first importance to all business interests that half the export surplus be turned into cash as speedily as possible. A tie-up of the grain movement means great inconvenience and in some cases disaster.

“The real solution is the utilisation of the alternative Pacific Coast route. It is logical that all grain west of Moose Jaw go that way and no time should be lost in organising the movement and the trade. The West has a moderate crop, some 200,000,000 for export, yet there is trouble ahead in its transportation. Had it been a bumper year with 300,000,000 to sell, existing difficulties would have been greatly accentuated.”

How many of us have any idea of the causes which go to make up congestion in traffic in Western Canada? Taking the cereal crop of Canada for 1921 as 288,493,000 bushels, we have 288,493 carloads at 1,000 bushels to the car, which divided into trains of 20 cars each, will give us 14,449 trains of cars loaded with grain. At 53 feet to the car we would have five trains to the mile or a single train 2,889 miles in length. As there are only 365 days in the year, if the entire crop had to be handled through Montreal on a single track, it would be at the rate of about 40 trains a day or nearly two every hour. As there are still 37 million acres in easy reach of the railways in Western Canada, and hundreds of millions as yet untouched and which yet have to be developed, the folly of handling the crops of the future, not to speak of the present, overland and by only one ocean route can easily be realised.

Assuming, then, that the export traffic of Canada in the future will move west as well as east, there is an important point

to consider which is bound to affect immensely the development of the West as against the East, and in the end develop our Pacific ports to an extent as yet undreamt of. It has been estimated that the arable land of what may be called Pacific or Western Canada comprises 333,000,000 acres as against 160,000,000 in Eastern or Atlantic Canada. On this basis it is evident that with the development of traffic westwards and *via* the Panama Canal, the products and traffic of Pacific Canada may double that of Atlantic Canada. This is one of the results to be expected from the awakening of the Pacific.

Let me at this stage give some idea of the awakening process as it has already become very evident in British Columbia. It was on the 7th November, 1885, at the little station of Craigellachie in the Eagle Pass in the Gold Range, in British Columbia, that the rails from the Atlantic met those from the Pacific, and the last spike was driven by Donald Alexander Smith, afterwards Lord Strathcona. As the hammer strokes fell those present felt that they were witnessing the crowning act in the creation of the Canadian Confederation and the welding together of a new nation. Queen Victoria cabled her congratulations to the Canadian Pacific Railway on the completion of a work "of great importance to the British Empire." It was that, and much more. It was the completion of the north west passage by land, just as the Panama Canal is its completion by water, and a world event of the very first importance.

Although not two score years have elapsed since the echoes of Donald Smith's hammer were heard in the narrow gorge at Craigellachie, there are now many great trans-continental railways with terminals at Vancouver, and ocean steamship lines to all parts of the world.

Vancouver and Victoria are served by both the Canadian National and Canadian Pacific Railways; the Northern Railway from Washington; the Great Northern, Northern Pacific, Chicago, Milwaukee and St. Paul; Union Pacific, Pacific Great Eastern, and a number of other American lines. Practically all ocean steamship lines operating on the Pacific use the ports of Vancouver and Victoria. These lines include the Atlantic Line to California; the Blue Funnel Line to Japan and China, and *via* the Panama Canal to London and Liverpool; the Border Line Transportation

Company to the State of Washington; the Canadian-Australasian Royal Mail line to Honolulu, New Zealand and Australia; the Canadian Government Merchant Marine, Ltd., to Australia, New Zealand, India, China and Japan; the Canadian Pacific Steamships, Ltd., to Japan, China, Washington, Prince Rupert and Alaska; the Royal Mail Holland-America Service and the Furness Prince Service both running to the United Kingdom and the Continent; the Canadian Robert Dollar Steamship Co. to China, Manila and Singapore; the "Harrison Direct" line to Seattle, San Francisco, Los Angeles, *via* the Panama Canal to Liverpool, London and Glasgow; the Johnson line to France, the United Kingdom and Stockholm; the Isthmian Steamship line from the Pacific Coast ports to New York and the United Kingdom; the Osaka Shosen Kaisha line to Japan, China, Vladivostok, Singapore and Bombay; the Pacific Steamship Company to Californian and Alaskan ports; the Union Steamship Co. to British Columbia and Alaska; the Société Générale de Transports Maritimes to the Mediterranean; and, from Victoria only, the Nippon Yusen Kaisha Line to Japan, China and Manila. There are now 34 regular deep-sea shipping lines operating into Vancouver as compared with 12 in 1914.

Esquimalt, close to Victoria, and Prince Rupert, the Pacific terminus of the Canadian National Railway, are becoming of greater importance yearly.

There has been a great increase in the shipping activity of the Port of Vancouver during the past year or so. The Canadian Pacific Railway Company has established the passenger and freight liners, the "Empress of Russia" and "Empress of Asia"; the "Empress of Canada" will leave the Clyde for her Pacific Station in February, to be followed by the "Empress of Australia." These are amongst the first steamships in the world. Similarly the Canadian Government Merchant Marine, Ltd., have instituted important new services. Besides inaugurating regular services to Japan, China, New Zealand and Australia, they have despatched the "Canadian Prospector" and "Canadian Traveller," with mammoth cargoes of timber to Egypt, India and South Africa.

For the fiscal year ending March 31st, 1918, the number of sea-going vessels outwards and inwards, and of coasting vessels outwards and inwards at Vancouver, was 22,985 with a total registered tonnage of 10,890,748

tons. In 1900 only 3,441 vessels of 13,699,238 tons gross measurement passed through the Suez Canal. A comparison of these figures will give some idea of the vast development of shipping and trade on the Pacific Coast since the Canadian Pacific Railway inaugurated its trans-Pacific line in 1887.

When it is considered that the last spike in the rails connecting Vancouver with Eastern Canada was driven by Lord Strathcona at Craigellachie in 1885, and that the site of Vancouver was an almost unbroken forest as late as 1885, and that the Canadian Pacific directorate did not decide to inaugurate its trans-Pacific services to China and Japan till 1891, only thirty years ago, it cannot be long before Vancouver becomes the Liverpool of the Pacific and Victoria and Prince Rupert great ocean ports.

One of the most remarkable developments on the Pacific Coast within the last few years has been in shipbuilding. Prior to 1917—only four years ago—not a single ocean-going ship had been built in British Columbia. By January, 1920, 90 wooden ships, 40 of them for the French Government, had been constructed, with a total tonnage of 217,900 tons, and 31 steel steamers of 207,900 dead-weight tons, a total of 121 ships of 425,800 dead-weight tons, had been constructed, and a number have been launched from the ways during the last year. The total already reached is 600,000 tons.

Pulp and paper manufacture was not established on a commercial basis till 1912. Since then seven pulp mills have been established. British Columbia already ranks third in this industry amongst the Provinces of Canada. The output for 1919 was sulphite, 8,047 tons; sulphate, 9,473 tons; ground wood, 99,769 tons; paper and news-print, 123,607, and wrapping paper 7,202 tons. She possesses 300,000,000 cords of spruce and other pulp woods, the largest stand of pulpwood in the world, with water powers near ocean navigation. In a very short time British Columbia must rank first among the Provinces of Canada as a pulp and paper producer.

Until 1897 the famous Okanagan was a land of bull pines and sage brush. Irrigation was introduced and the first orchard in the district set out that year. This season British Columbia has produced 3,027,000 boxes of apples. British Columbia fruit

won its first gold medal at the Royal Horticultural Show in London in 1904. She also carried off the gold medals in 1906, '7, '8, and '10, and in 1910 won the highest fruit prize in the Empire, the Hogg Memorial Gold Medal. At the Imperial Fruit Show just closed she won seventeen medals, or more than all the other Provinces of Canada combined.

Salmon canning as a business was first undertaken on the Fraser River in 1870. The largest pack of salmon in British Columbia was in 1918, when the total of all species was 1,616,157 cases. This represented 17,777,727 fish on a basis of 11 fish to the case; in pounds 78,575,536, the standard weight of fish in a case being 48 pounds net. The production of fish in 1919 was 44.7 per cent. of all Canada.

British Columbia is the western front of the British Empire on the Pacific Ocean, and I have referred to several evidences of the awakening processes going on there. But the awakening of the Pacific means much more than the activities of any one country. It is the awakening of the world's great giant. Gulliver, when he visited Brobdingnag, the country of gigantic giants, found that he was a pigmy "not half so big as a round little worm plucked from the lazy finger of a maid." The Pacific Ocean doubles the Atlantic in area. With the Indian Ocean and its tributary seas it more than trebles the Atlantic area. It exceeds in compass the whole of the four continents. On its shores and innumerable islands dwell two-thirds of all mankind. There lies the Imperial Pacific Dominion with nine-tenths of British possessions. There is not a settlement, no matter how remote, in the great Pacific world but feels to-day the heart throb of new and vigorous life. Japan, India, China, Australia, New Zealand, Oceania, South America, the United States, Canada—all are pulsing with new life and enterprise, and actuated by high aspirations and great hopes, due in no small degree to the opening of the Panama Canal. In April last it was predicted in the Canadian House of Commons that before two years the commercial and political centre of the world would pass from the Atlantic to the Pacific. It is already the centre of world politics. How long will it be before it becomes the centre of the world's commerce before British Columbia becomes the imposing entrance portal of Canada, instead of what it was at one time, its postern gate?

What part is British Columbia to play in the great awakening which has already begun, in the most momentous event of the twentieth century? The whole answer depends upon the resources which she is able to contribute to this giant development, particularly upon the stores of energy which she is able to employ. The list of these is formidable:—

Timber. 400 billion feet.

Coal. 75 billion metric tons.

Waterpower. Total for ordinary minimum flow, 1,931,142 horse-power; maximum development dependable for six months, 5,103,460 horse-power.

Iron. Magnetite equal to best Swedish ore, and hematite of best grade, estimated three million tons.

Some of the staple-products are:—

Agriculture, 1919	\$61,000,000
Forest, 1919	\$70,000,000
Minerals, 1918	\$41,782,474
Fish, 1917	\$21,518,595
Total Mineral product, including 1918	\$637,358,581

Last, but by no means least, climate and sunshine. Vancouver Island has been called the "Madeira of the Pacific." British Columbia is the Riviera of Canada.

It lies between parallels of latitude 49° and 60°, where the best things grow. The Japanese current, the mountain barriers against the East and West winds, and the ocean tides of the Pacific produce an unequalled climate.

The average temperature in the coldest month (January) is 39° Fahr. at Victoria. The average temperature in the warmest month (July or August) is remarkably cool—60° at Victoria. Bright sunshine on the coast is 2,068 hours, or more than in Great Britain or even the Channel Islands.

As Captain Vancouver said 140 years ago:—

"To describe the beauties of this region will, on some future occasion, be a very grateful task to the pen of the skilful panegyrist. The serenity of the climate, the innumerable pleasing landscapes, and the abundant fertility that unassisted Nature puts forth, require only to be enriched by the industry of man with villages, mansions, cottages, and other buildings to render it the MOST LOVELY COUNTRY THAT CAN BE IMAGINED, whilst the labour of the inhabitants would be amply rewarded in the bounties which Nature seems ready to bestow on cultivation."

(Following the paper several series of cinematograph views were exhibited)

THE CHAIRMAN (the Duke of Devonshire), wished, on behalf of those present, to thank the author very deeply and sincerely for the admirable paper and illustrations. They recalled to him many interesting and happy memories. One point he wished to lay emphasis upon was the fact that only about a third of the country had been yet touched at all. The figures Mr. Wade had given were very striking but there was much within the region which had not been explored in Vancouver Island for example. The great district of the Peace River was only just opened, and when that was connected with the coast it would add enormously to the knowledge possessed at the present time. When he saw on the film that absolutely marvellous timber being smashed up to be made into newspapers it filled him with horror. Newspapers he supposed were necessary or desirable, but still he thought a better fate should await some of that beautiful timber. Wonderful as had been the progress in a short time, the next 10 to 25 years were going to see still more marvellous development and the contribution Mr. Wade had made that afternoon would stimulate great interest in the subject. He was sorry that owing to a prior engagement he would have to vacate the chair and leave the meeting.

The chair was occupied for the remainder of the meeting by Sir George R. Parkin, K.C.M.G., LL.D., D.C.L.

DISCUSSION.

SIR GEORGE PARKIN, K.C.M.G., LL.D., D.C.L., said he thought it was very valuable that the people of this country should have their imagination stretched to understand the amazing changes which were taking place in different parts of the Empire. The vivid way in which Mr. Wade had put forward his facts must have impressed everyone. He should like to add to what the author had said something about the extraordinary national importance of the things which were happening on the Pacific Coast. The author naturally, as representing British Columbia, had brought forward the resources of that country, but it was necessary to understand also the great importance of it to Great Britain. The author had referred to the lop-sided development of the American Continent. He (Sir George Parkin) should like to dwell as a Canadian on the kind of energy which was thrown into correcting that lop-sided development. A little before the year 1886, when the Canadian Pacific Railway was started towards the West, there was practically more than 2,000 miles of country without any civilised population whatever with the exception of one or two small towns. America a few years before had built

a railway across the Continent. There were 20 million people on one side of the Continent and 2 million on the other, before America dared to face that problem, and yet Canada faced it when there were only $3\frac{1}{2}$ millions on the East and only 50,000 in British Columbia. That gigantic task of crossing the uninhabited country was faced in order to open up a connection. The man whose pluck and energy had more to do with it than anyone else was Lord Mount Stephen, whose death at the age of 92, had just occurred. His great colleague, Lord Strathcona, died only a few years ago. It was the pluck and energy of a few men that carried through such an unexampled enterprise, unexampled whether from the engineering point of view, the contractors' point of view, or the great political effort made by the nation. The result should be noticed. The greatest Conference the world had ever known was sitting in Washington to-day, and while dealing with some things that concerned the Old World was primarily dealing with the vast problems of the Pacific. Everyone knew that the balance of the world was shifting from the Atlantic towards the Pacific. Any vast development of the future either of the British Empire or commerce generally or of the world at large, was going to take place mainly on the Pacific. It was the energy of the men referred to and the effort that Canada made at that time that gave the Dominion a great front on the Pacific. While minor processes were going on in New Zealand and Australia, Canada was now standing face to face with the great problems of the Pacific and had a large part to play in the enormously expanding range of human energy in that region, and with the vast populations of the East. The author also referred to the great granary of the West, perhaps the most important ever known, and had pointed out how the opening of the Panama Canal had changed the whole prospect of emptying that overflowing granary into the world's markets, and particularly into the United Kingdom. So vast was the country and so enormous its possibilities for grain production that not only was Canada going to make use of the sea route the author had spoken of, but had also undertaken to create a other sea route, and she had almost completed a railway which gave the chance of two or three months' communication through the Hudson Bay, in order to have an outlet for the enormous resources of the North-West in grain production. He could remember distinctly when it was thought that the line of wheat production was well south, but it had been extended much further north in districts where it could not have been grown a few years ago. Moreover, he was told the other day that scientific research had now developed a wheat that ripened about a fortnight sooner. For years he worked with his old friend Sir Sandford Fleming, on the question of the great Pacific cable crossing to New Zealand and Australia.

Sir Sandford then said that the time would come before many years when the Pacific would be crossed by many cables. As a matter of fact the United States had been compelled to make lines, and in the vast commerce which was sure to develop there would be cable communication on a large scale. It was British Columbia which was giving the British Empire, unless the place of the cable was taken by wireless communication. Facing the Pacific it was a most important thing that the tide of the British population of the best kind should settle on that coast. There was there one of the purest British populations established anywhere, while in the central prairies there was a mixed population from Galicia, Russia, and a hundred different points. It was providential that on the two sides of Canada East and West, there should be two of the most strictly British populations that could be found anywhere in the world. A thousand things were suggested to anyone who knew the country. He had been interested in seeing the big trees on the screen. He was in Vancouver a few years ago and met an old pupil managing a great mill. Some of his old boys were showing him the sights and gushing a great deal about British Columbia as everybody did, and it was said to him: "At our mill we used two tons of gun-powder last year to blow off the sides of the trees so that we could get them into the mill." He was entirely prepared to consider the story as a sort of joke, but next morning he drove with his friend down to the mill and saw the logs, with the sides blown off, being cut by two circular saws one above the other. There was no doubt at all that for the lecturer to come to the Society and show the development going on in British Columbia, developments which materially affected the British Empire, was a very important thing.

MR. PERCY HURD, M.P., wished to echo the cordial words of appreciation that had been spoken with regard to the paper. He was in British Columbia last year with his wife and they were astounded at the wonderful potentialities of that portion of the Dominion and also at the happily developed British characteristics there. At Duncans there was a large British community, and when the Imperial Press Delegates arrived at the handsome reception hall they found the luncheon tables set out in sections. There were separate tables for English, Scotch, Welsh, Australians, Indians, and so on. Being English himself and his wife Scotch they were separated, each having to take places amongst the race to which they belonged. That was an illustration of what Sir George had said, that there was in that section of the Dominion essentially a British development going on. And this development had its serious political aspect. There was no doubt whatever that in the development of the Empire, while it was necessary to bear in mind the implications of an Empire which had a

coloured population, it was necessary also never to forget that the foundations of progress of the Empire and the world lay in keeping as British as possible the elements of the population overseas. That raised many difficult questions which the author had most prudently kept out of his paper, but in looking at the emigration problem which was forcing itself to the front, owing to industrial conditions here and the adopted policy of the Government, it was necessary, especially on the part of those in the House of Commons who had to deal with votes and estimates, whether for emigration or fostering Empire export business, to remember that after all we were a great Empire family and to take care that our money and energy were applied so that the traditions which had made the British Empire great might keep it great in future years.

SIR GEORGE PARKIN said there was now constant connection between Vancouver and New Zealand and Australia. It gave an alternative route to those countries and he did not know anything more advantageous to the Empire than that Australians and New Zealanders in coming to England or returning home should have an opportunity of crossing Canada and seeing its advantages. It would create that intimacy which was going to make the Empire more consolidated even than before.

COLONEL SIR CHARLES YATE, Bt, C.S.I., C.M.G., M.P., in moving a vote of thanks to Mr. Wade for his paper, said he thought it would be readily acknowledged that the imagination of those present had been well stretched. It was beginning to be realised what Canada really was. As an old Indian he had taken particular interest in what had been said with regard to the communications from Vancouver not only to Australia and New Zealand, but to India as well. He was delighted to learn from the paper that the Canadian Government Merchant Marine was now running a regular steamship line from Vancouver to India, and he hoped it would progress year by year. The population question was a serious one. In Canada, as they had just been told, there was a mixed population in the interior, with a British population at each end. All he could wish was that that mixed population should be swamped by a British population at the earliest possible moment. It was to be hoped that under the present scheme of assisted emigration for ex-soldiers and others so many Englishmen would be poured into Canada that the mixed population would be reduced to a minimum as time went on.

MR. PERCIVAL A. HEITLAND (Furness Shipping Co., Ltd.) in seconding the motion, said there was one point in connection with the opening of the Panama Canal and the opportunities that arose for the development of Western

Canada to which he should like to allude. Throwing the mind back to the time when the Panama Canal was not open, before the war, one could imagine if the war had never taken place there would have been in Canada a wonderful system of trans-continental railroads providing cheap land transport, and the opening of the Panama Canal would have furnished in addition the cheapest known means of transport, namely, by water. On the sea it was practically impossible for keen competition to be eliminated by any sorts of combinations or conferences for any great length of time; in the long run everyone had to come down to the lowest possible figure at which an ocean vessel could be operated. That was all to the good of communities which lived and worked in the vicinities of tidal waters. The figures given by Mr. Wade were sufficiently striking in themselves, but it was almost impossible to overestimate them, because railroad companies the world over had problems to deal with in getting down their cost of operation per ton mile, which were greater than any corresponding problem which the ocean operator had to deal with. All the railway development in Australia had been coastal with the idea of bringing the traffic from the developed coastal areas to the deep-water ports. It would be a big and somewhat doubtful undertaking to drive trans-continental railways through Australia and it was questionable whether they would be economical or helpful for a good many years to come, because of the wonderful advance in the race which other countries had already made in supplying Europe with raw materials and foodstuffs, particularly Canada.

The motion was carried unanimously.

MR. WADE returned thanks, and the meeting closed.

WATER POWER RESOURCES OF THE UNITED KINGDOM.

The final report of the Water Power Resources Committee has been issued as a Blue Book, and consists of 178 pages, together with a series of elaborate maps illustrating the text. The Committee were appointed in 1918 by the then President of the Board of Trade, Sir Albert Stanley, M.P. (now Lord Ashfield, of Southwell) "to examine and report upon the Water Power Resources of the United Kingdom and the extent to which they can be made available for industrial purposes," and comprised, Sir John Snell (Chairman), Mr. G. S. Albright, C.B.E., Mr. H. F. Carhill (Board of Trade), Sir Dugald Clerk, K.B.E., F.R.S., Dr. J. F. Crowley, Major Sir Philip Dawson, M.P., Professor A. H. Gibson, Dr. H. R. Mill, Mr. A. Newlands,

C.B.E., Mr. G. C. Vyle (representing the Associated Chambers of Commerce and the Federation of British Industries), Mr. Ralph Walter (Ministry of Reconstruction), and Mr. D. J. Williams. In 1919 the Committee were instructed to consider further "what steps should be taken to ensure that the Water Resources of the country are properly conserved and fully and systematically utilised for all purposes," the following fresh members being added on the nomination of the Minister of Health: Sir Frederick J. Willis, K.B.E., C.B. (Chief Assistant Secretary of the Health Ministry), Mr. E. A. Sandford Fawcett, C.B. (Deputy Chief Engineering Inspector of the same department), Mr. A. B. E. Blackburn, M.Inst.C.E. (President of the Institution of Water Engineers), Mr. E. Sandeman, M.Inst.C.E., and Mr. W. A. Tait, M.Inst.C.E. Sir John Purser Griffith, M.A.I., M.Inst.C.E., was made an extra member, Mr. E. M. Konstam, C.B.E., K.C., succeeded the late Mr. A. J. Walter, K.C., and Lieut.-Col. D. Watts Morgan, M.P., took the place of Mr. Vernon Hartshorn, M.P., who resigned owing to pressure of Parliamentary and other duties. So far as Ireland is concerned the investigations were conducted by a Sub-Committee appointed directly by the President of the Board of Trade.

Realising that with the limited financial means at their disposal, it would be impossible to undertake a complete survey of the water power resources of the country, the committee concentrated upon obtaining particulars of as many schemes as possible for utilising particular sources which appeared likely to prove commercially practicable. Actual surveys were undertaken in a number of areas, and schemes from Government Departments and other sources were also examined.

Upwards of 50 witnesses were called. The reports and evidence obtained, which do not purport to be exhaustive in any way, establish a *prima facie* presumption that some 210,000 kilowatts (one kilowatt = $1\frac{1}{2}$ electrical horsepower) in the form of electrical energy could be developed continuously day and night through out the year at an economic rate from those British schemes which were considered.

It is pointed out in regard to Great Britain that the potential electrical output of the commercially practicable schemes is equal to about 40 per cent. of the total output in the year 1917-1918 of the 410 British public electricity supply and electric tramway and railway undertakings operated by steam power; also, that the development of this amount of energy in steam stations would involve the consumption of nearly 3 million tons of coal per annum.

The Irish Sub-Committee consider that from a portion only of the water power resources of Ireland a continuous output of 11,300 kilowatts could be secured.

The bulk of the larger British water powers are situated in the Scottish Highlands, and although this district is some distance from the present great industrial centres, no part of it is far from the sea or the Caledonian Canal. It is suggested that the utilisation of the Scottish water powers might do much to arrest the depopulation of the Highlands.

The larger water powers of Wales are situated in the North Western part of the Principality. The proposals of the North Wales Power and Traction Company, Limited, which involve the utilisation of several larger water powers in this district for public electricity supply purposes have already received the approval of the Electricity Commissioners.

In England, the main sources of water power are the small falls on rivers, and although the power available at any particular site is small, the aggregate output that might be produced by improving these sites, by installing modern turbines in the place of inefficient plant at existing sites, and the general improvement of the water courses is considerable. As a typical case, the Wiltshire Avon is cited. At present, plant is installed or about to be installed to generate in the aggregate 650 kilowatts, but investigation showed an *additional* output of 2,300 kilowatts could be procured. An examination of the Lake District did not reveal any large water power capable of commercial development.

The Committee consider that every inducement should be given to persons interested in power production to utilise for their requirements a perennial source of energy like water power, rather than a wasting asset like coal, and they recommend that the collection and publication of information regarding potential water powers should continue, and that financial assistance might be afforded by the State to water power undertakings during the difficult years of the constructional period.

A haphazard harnessing of the country's water power may, however, lead to partial developments which would prejudice the ultimate complete utilisation of the available resources and thus result in considerable waste. It is necessary, therefore, that some control over development should be exercised in the national interest. The Committee consider further that provision should be made for the ultimate acquisition by the State of all future water power undertakings, and they propose a system of terminable licences usually of long term for limiting the tenure of the undertakers of water power developments.

It is suggested that either the Board of Trade or the Electricity Commissioners, should, be

specifically charged with the duty of studying, supervising and promoting the development of water power.

As regards Tidal Power, the Committee reiterate the recommendation made in their Third Interim Report, that this subject be specially studied by a Technical Commission with particular reference to the Severn Estuary, in regard to which a considerable amount of information has already been accumulated.

A great number of different interests are concerned in the available supplies of water. The predominant requirement is necessarily an adequate supply for domestic and sanitary purposes, but in any proposal involving the use or abstraction of water, the claims of steam and water power plants, trade and industrial consumers and canals and navigable water-ways need to be considered, and the prevention of pollution, the protection of fisheries, and the needs of agriculture from the standpoints of land drainage, irrigation and watering of stock have to be borne in mind. In Scotland the water resources are, comparatively speaking, abundant, and the population over considerable areas is sparse, and in consequence the conciliation of opposing interests can be effected by the Government Departments concerned, most of which are responsible to one Parliamentary head, the Secretary for Scotland. In England and Wales, however, the increase of population and the growing requirements of industry are responsible for a steadily increasing demand for water, and the problem of meeting future needs is giving rise to considerable anxiety. The Committee recommend, therefore, that a Water Commission having jurisdiction over England and Wales should be appointed mainly for the following purposes:—

- (i) Subject, in case of opposition, to Parliamentary sanction, to allocate the water resources of England and Wales in the general interests of the community and to re-adjust existing allocations of water where hardship or anomalies are shown clearly to exist.
- (ii) To adjust conflicting interests in connection with the use of water for a particular purpose.
- (iii) To afford assistance to Parliamentary Committees before whom Bills relating to water may be heard, and to Government Departments concerned in the use and control of water for specific purposes, and also to the various local authorities and water supply undertakings.

It is also proposed that the existing local Boards and other bodies concerned with the separate water interests should be replaced by Boards, set up by the Water Commission, having general supervision over the water resources in a particular river basin or group of river basins. An Inter-Departmental Water Committee would serve to keep the Departments

concerned with the various water interests in touch with one another and with the Water Commission.

The Committee consider that the Commission, in addition to promoting the actual conservation of the water resources of the country, would secure their more economical development by promoting joint action between water-supply authorities, by lessening the cost of the necessary inquiries into proposals for allocating water, and by centralising the collection of data relating to water resources. It is proposed, therefore, that the expenses of the Water Commission should be defrayed in part by a levy on the water undertakings in England and Wales, and in part by the fees of applicants for powers to undertake works.

Appended to the report are a "reservation" by Mr. Fawcett and a communication to the President of the Board of Trade, from Mr. Tait, both of whom disagree with the majority as to the formation of a Water Supplies Commission. *Inter alia*, Mr. Tait says: "Public opinion, already resentful at the number of permanent Departments or Offices, will be strongly opposed to the proposal as involving further expense to the taxpayers."

NOTES ON BOOKS.

THE VAN EYCKS AND THEIR FOLLOWERS By Sir Martin Conway, M.P. London: John Murray 1921 £2 2s

More than thirty-seven years ago Sir Martin Conway was studying, writing and lecturing upon Early Flemish artists. He has also written many books on kindred and other subjects, such as explorations of mountainous regions in far northern Europe, in Italy, in north-west India (the Karakoram Himalayas), in Tierra del Fuego. His distinction as an explorer and traveller, indeed, is even greater than that in other directions, where his authority is duly recognised. His peculiar qualifications for compiling a work on "The Van Eycks and their followers" is unquestionable. Chapter I. opens with a sketch of the "Gothic Age," and conditions favourable to the development of art, especially that of painting in the Low Countries, France, and the Rhineland: but the stated purpose of the book—it contains over five hundred pages and about one hundred illustrations—is "to open the way for the ordinary 'intelligent person to enter into this particular domain of art and there orient himself and find a solution of such difficulties as are to be encountered on the threshold.'" Like other historians of painters—Vasari, Horace Walpole, Crowe and Cavalcaselle—Sir M. Conway has (as they did in their day) made use of available materials and researches, paying special tribute to the work of recent date by the late Mr.

W. H. James Weale (whom he regards as the founder of the study of the van Eycks and their followers), and to that by Dr. Friedlander and Professor Hulin, "the two most eminent of the later generation of workers." He supplements his considerable adaptations of their dissertations with his own capital notes, observations, reminiscences, etc., of which he has an evidently considerable store.

The range of his exposition covers a period of nearly two hundred years, beginning with Hubert van Eyck (1366-1440) and ending with Peter Breughel (1510-1570)—who, Sir Martin considers, stands "as much alone in the mid-sixteenth century as the van Eycks at the beginning of the fifteenth; gives all three, opening and closing the long procession of 'lesser men who connected them.'" That eminent authority, Crowe, has written that "if the personal influence of the van Eycks was smaller than of their work was immense, and it is not too much to say that their example taken in conjunction with that of Van der Weiden determined the current and practice throughout the whole of Europe north of the Alps for nearly a century." Under such circumstances one does not detect distinctly that *air de famille*, which, in Sir Martin Conway's opinion, presumably should relate the work of a van Eyck with that some hundred and fifty years later of Bernard van Orley, for instance, "whose large pictures are unsympathetic to me" "his ability is obvious"—"We do not like you, Dr. Fell is the attitude of most of us;" so writes Sir Martin somewhat sweepingly in his remarks upon the famous master, from whose designs (a single series of many others) the tapestries of the *Chasses de Maximilien* were worked, and hang splendidly on the walls of the *Galerie des Cerfs* at Chantilly. Even more sumptuous in effect of metallic glitter and rich colour like a missal painting of a Gothic style, are the David and Bathsheba tapestries in the Cluny Museum, the designs for which were adapted from paintings by such an artist as R. van der Weyden (Roger de la Pasture), who worked in the century before that of Bernard van Orley. Now it is well to bear in mind that a large proportion of the designs for earlier tapestries, such as those of the fourteenth and fifteenth centuries is due to enlarged versions of Missal illuminations or miniatures as they are sometimes called; and the first illustration in Sir M. Conway's book is a photogravure of an exquisite illumination by Hubert van Eyck. He was born "under the shelter or protection of a Benedictine Convent, in which art and letters had been cultivated from the beginning of the eighth century." Hugo van der Goes, a distinguished disciple of the van Eycks, was also a member of a conventual community. A cursory view of the historic continuity of painting necessarily embraces the activity of monastic establishments

in rearing painters of illuminations, whose work is, as we point out, immediately related to cognate later work on the larger scale, exemplified in frescoes and tapestries. To such an important stage in the evolution of European painters as this, Sir Martin seems to us to refer lightly, as it were, *en passant*. His main object is, apparently, to discuss minutely personal styles of certain notable painters (within a proscribed period) of panels and easel pictures.

The numerous small scale black and white illustrations in the book cannot, of course, convey, colour effects, but they supply good indications of mannerisms of drawing and composition, light and shade, etc., by means of which typical features in the works of various masters, mostly "lesser men," may be compared. On these Sir Martin does not stint his opinions and criticisms: the fluency and volubility with which they are expounded furnish us with much engaging reading. Notwithstanding that the fascination, yielded by an abundance of stimulating assertions, deduction and pleasant anecdote, may lead some mere investigators who are *in limine*, "on the threshold," to miss, in a Shandean manner, the actual track of the "van Eycks and their followers," Sir Martin Conway may surely be cordially thanked for having brought the results of his prolonged and interesting labours before the public.

IMPERIAL WIRELESS COMMUNICATION.

At the conclusion of the War, it was decided to complete the wireless stations at Leafeld, in Oxfordshire, and at Cairo, and so make a real start with the proposed "Imperial Chain." At the same time, a Committee was appointed to consider the best ways of applying modern engineering knowledge to Imperial wireless telegraphy. This committee produced a scheme in due course, and in accordance with its recommendations, the planning of the various stations was subsequently referred to a small commission, of which Viscount Milner, then Secretary of State for the Colonies, was Chairman, and Dr. W. H. Eccles, F.R.S., Vice-Chairman. The construction of the stations was entrusted to the Engineering Department of the General Post Office, and corresponding departments overseas. The report of the Commission has been submitted to His Majesty's Government for consideration by the Cabinet, and will, it is expected, be published in the near future. Meanwhile, Dr. Eccles has performed a useful service in placing before the readers of *The Times* a broad statement covering the preparatory work that has been accomplished in connection with this undertaking.

Six principal stations are projected:—Great Britain, Australia, South Africa, India, Canada and New Zealand. Full consideration of the last two was postponed, owing to geographical conditions. An equilateral triangle some 5,000

miles along each side is formed by Australia, South Africa and India. The distances of Great Britain from South Africa, India and Australia, are respectively 6,000, 5,000 and 10,000 miles. To provide against interruptions from unfavourable weather, intermediate relay stations are designed, as well as instalments of thermionic valve plant for the purpose of generating electric waves, "which should be capable of adaptation at will to ranges varying from 2,000 to 11,000 miles, and capable of easy variation in strength from moderate to very intense, according to atmospheric conditions." Besides being strategically important it is anticipated that the intermediate stations will develop a local traffic.

The complete plan of the Committee contemplated an African branch, a separate Eastern branch, and, to assist British interests in the Far East, a station at Hong Kong, the last named to be worked as an off-shoot of Singapore.

In conclusion, Dr. Eccles adds that universal wireless progress during the 18 months which have elapsed since the Imperial Wireless Telegraphy Committee formulated their scheme has tended to confirm their conclusions that an Empire wireless service can be made continuous and trustworthy at reasonable cost by aid of the intermediate relay stations, and that only in this way can we escape the partial and erratic service which must accompany attempts at direct communication across the immense distances separating the chief centres of the Empire.

THE NICKEL RESOURCES OF CELEBES.

Much time has been spent in the exploration of nickel deposits in Celebes, according to the *Netherlands Indies Review*, and although it is not yet possible to illustrate the economic importance of such resources in figures, there is sufficient ground for considerable optimism.

The widely varying content on the one hand, and the absence of any system of measuring deposits on the other, renders it impossible to arrive with any certainty at an estimate of the available nickel ores in the island, and no attempt has yet been made to determine the minimum working content of each ore field or the costs of extraction. The usefulness of low-lying districts is entirely ruled by cost of transport.

Generally speaking, each nickel ore deposit consists of a few thousand tons in the form of nickel silicates, containing from 3 to 8 per cent. of nickel. Several deposits of this nature have been discovered, and in several places, a large number of veins close together make the fields of considerable importance.

In 1912, 800 concessions were granted in New Caledonia, and the production in 1911

and 1912 respectively was 152,000 tons and 108,000 tons, 120,000 tons and 72,000 tons of which were exported, and about 30,000 tons were worked up each year on the spot. The average content of the exported ore was 6 to 7 per cent. of nickel.

The falling off in production in 1912 was ascribed partly to the large stocks held in Europe, and partly to the high freights, which soon swamped the profits on an article which was valued by the Customs at 25 and 38 francs a ton. During the war, the production remained at about the same level, but owing to the shortage of tonnage the export of large quantities was impossible, and only 49,000 tons in 1915 and 31,000 tons in 1916 left the island.

As might be expected, efforts have been directed in New Caledonia towards the production of a substance containing more nickel. In 1912, two plants were smelting the nickel ores with sulphur ores in cupel furnaces to a matte containing from 40 to 50 per cent. of nickel, while a third, using hydro-electric power, employed an electro-metallurgical process. This last mentioned plant produces a ferro-nickel with about 50 per cent. of nickel. The commercial value of the matte, f.o.b. New Caledonia in 1912, was 700 francs a ton, and that of ferro-nickel considerably higher, not only because it contained more nickel, but also because its composition was such that it needed only one refining treatment to make it into a commercial product of general applicability, while the matte as a rule required at least two processes.

The water-power station in New Caledonia, with a capacity of 15,000 h.p., for the purpose of supplying a new smelting plant, not only to make ferro-nickel, but also to produce ferro-chrome direct from the ores, has proved its utility. The treatment direct of nickel silicates has not been undertaken in other countries with the help of electric furnaces.

Besides the preparation of ferro-nickel containing from 40 to 50 per cent. of nickel, a steel works in Central Celebes would be in a position to supply not only alloy steel containing about 1 per cent. of nickel and a smaller quantity of chromium, but also nickel containing from $1\frac{1}{2}$ to 3 per cent. of nickel. Where the nickel ores contain a large percentage of magnesium they may be used for the production of a slag.

This shows how advantageous it is that the working of nickel should be carried on side by side with the steel industry. If the two operations are separated it will undoubtedly lead to increased expenses. The persons who supervise the metallurgical treatment of the iron ore can do the same in the case of nickel. A beginning can be made on a small scale and even should the venture not prove a success, which is extremely improbable, the staff, works—even the furnaces—can be put to other use.

GENERAL NOTES.

AUTOMATIC SUPPLY OF PETROL FOR MOTOR CARS.—A station for the automatic supply of petrol to motor cars is now being constructed on the Quay de Passy, Paris. The system has been in use in the United States for several years, and the Paris cisterns are a copy of those in use on the American roads. These roadside stations are simply tanks fitted with a feed pipe, and the quantity of petrol furnished to a car is automatically registered by a recording dial. In this way there is no trouble with petrol cans, or the necessity of driving to a garage, and the process of filling is much quicker than by the usual way.

ELECTRIC POWER ON THE RIVIERA—It has been decided to utilize the water power in the mountains on the Riviera by the erection of a large power station. Sixty million francs will have to be provided for utilizing two water falls, one at Boucairon and the other at Saint Etienne de Jincé and erecting the necessary machinery. It is quite probable, if this is done, that this district will, in the near future, become an industrial centre, as at Grenoble and other localities in the French Alps, where large manufactories have been developed through the use of water power. It is intended that this new station will supply electric current to Nice and other towns on the Riviera.

THE FRENCH EXPORT TRADE—The improvement in French trade is shown by the continual increase in the exports, which during the first four months in 1921 in spite of the universal economic crisis, reached a total of 7,400 millions of francs, as compared with 6,288 millions during the same period in 1920. On the other hand, the imports during the same period decreased to 7,118 millions francs, thus showing an increase in value of exports over imports of 282. millions francs, instead of the formidable deficit of the first four months of 1920. These fresh indications of France's economic recovery should stimulate production and economy in that country.

CULTIVATION OF CHINESE TEA PLANT IN PARAGUAY.—In the Department of Villarica, Paraguay, there is a nursery for the cultivation of the Chinese tea plant and its adaptation in that country, according to "Commerce Reports," seems very propitious. Experiments to acclimatize Chinese tea have been made in Paraguay on former occasions with favourable results. There are two varieties of tea—Bohea and Viridis. The experiments with the former have shown that it is difficult to grow it in Paraguay; the latter, however, is readily acclimatized.

BOARD OF ARCHITECTURAL EDUCATION.—The Royal Institute of British Architects have published a short pamphlet containing advice to candidates for the Institute's Examinations, together with a list of books recommended to those who are studying architecture. This pamphlet may be obtained free on application to the R.I.B.A., 9, Conduit Street, W. 1.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, JANUARY 9. Geographical Society, 135, New Bond Street, W., 8.30 p.m. Sir Philip Brockdenhurst, "Across Wadai." Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Miss C. L. Maynard, "The Bible of the Twentieth Century." Surveyors' Institution, 12, Gt. George Street, S.W., 8 p.m.

TUESDAY, JANUARY 10. Petroleum Technologists, Institution of, at THE ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Civil Engineers, Institution of, Gt. George Street, S.W., 6 p.m. Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Lord Morris, "The Birth of the Overseas Empire and its Development." British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. A. Wilcock, "The Decorations of Versailles." Anthropological Institute, 50, Gt. Russell Street, W.C., 8.15 p.m. Mr. J. Whatnough, "Rehina, the Venetic Goddess of Healing." Metals, Institute of (Scottish Section), 39, Elmbank Crescent, Glasgow, 7.30 p.m. Dr. A. McCance, "Internal Stresses in Metals." Royal Institution, Albemarle Street, W., 3 p.m. (Juvenile Lecture.) Prof. J. A. Fleming, "Wireless Telephony." (Lecture VI.)

WEDNESDAY, JANUARY 11. Rubber Industry, Institution of, at THE ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6.45 p.m. Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. R. Stelling, "A Fair Day's Work for a Fair Day's Pay."

THURSDAY, JANUARY 12. Aeronautical Society, at THE ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 3 p.m. (Juvenile Lecture.) Major D. C. M. Hum, "Boats that Fly." Antiquaries Society of, Burlington House, Piccadilly, W., 8.30 p.m. Optical Society, at the Imperial College of Science and Technology, South Kensington, S.W., 7.30 p.m. 1. Dr. C. J. Peddle, "The Manufacture of Optical Glass." 2. Dr. J. W. French, "The Barr and Stroud 100-ft. self-contained Base Rangefinder." 3. Mr. T. Smith, "The Optical Three Apertures Problem." Historical Society, 22, Russell Square, W.C., 5 p.m. Mr. F. W. Buckler, "The Political Theory of the Indian Mutiny." Mechanical Engineers, Institution of (Midland Section), The University, Birmingham, 7.30 p.m. "Dr. Leonard Hill's Katathermometer." Metals, Institute of, at the Sir John Cass Technical Institute, Jewry Street, E.C., 8 p.m. Col. N. Belalew, "The Inner Structure of the Crystalline Grain." Central Asian Society, at the United Service Institution, Whitehall, S.W., 5.30 p.m.

FRIDAY, JANUARY 13. London Society, at THE ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 4.30 p.m. Lady Cooper, "The Banks of the Thames." Japan Society, 20, Hanover Square, W., 5 p.m. Mr. A. B. Malden, "Japan, the Flower of the East." Astronomical Society, Burlington House, Piccadilly, W., 5 p.m. Malacological Society, at the Linnean Society, Burlington House, Piccadilly, W.

Harry Goward Philip Venables, Esq.	2	2				

The above list includes all subscriptions received up to January 9th. Further lists will be published in the *Journal* from time to time.

*The first list was published in the *Journal* of December 2nd, 1921.

NOTICE.

NEXT WEEK.

WEDNESDAY, JANUARY 18th, at 8 p.m.
(Ordinary meeting), JULIAN S. HUXLEY,
M.A., Fellow of New College, Oxford,
"Recent Advances in the Determination
of Sex in Animals." PETER CHALMERS
MITCHELL, C.B.E., M.A., D.Sc., LL.D.,

F.R.S., Secretary of the Zoological Society of London, in the chair.

Further particulars of the Society's meetings will be found at the end of this number.

MANN JUVENILE LECTURES.

The first of the series of Juvenile Lectures under the Dr. Mann Trust, was delivered on Wednesday, January 4th, by Mr. William Reginald Ormandy, D.Sc., F.I.C., F.C.S., the subject being "Clay—What it is—Where it comes from—and What can be done with it." The Chair was taken by Sir Herbert Jackson, K.B.E., F.R.S.

Dr. Ormandy told the audience he did not propose to give a lecture, but preferred to call it a chat. He supposed they all knew what clay was, although it was very difficult to define it, because it consisted of so many things. Its one characteristic however, was plasticity, as the moment the right quantity of water was mixed with it, it could be moulded with the hands and would retain the shape given to it. He said we could not make a material plastic and that the plasticity of clay was something inherent—a property given to it by nature. Mankind, long ago, discovered the possibilities of utilising clay, for in the Book of Job it was stated that there were men who lived in houses made of clay, i.e., bricks made from clay, merely dried in the hot tropical sun. The Tower of Babel was also built of bricks that were burnt in the fire. There were references in the Book of Job, to potsherds (i.e. broken pieces of pottery) being used to scrape oneself with. The Egyptians and Assyrians and many other races used unburnt blocks of clay in making out their bills and accounts, etc. When they were brought over here, it was necessary, owing to our moist climate, to burn the tablets in order to preserve them. But they still retained their shape and from the inscriptions on them we were able to tell how the people of that age lived and what they did.

Kaolin, the scientific name for the purest sort of clay, was a Chinese word, and this kind of clay was brought over to England about the middle of the 17th century. From this clay the Chinese had for over 2,000 years made a porcelain equal in quality to anything we had been able to manufacture with all our scientific knowledge. It was rather extraordinary that at the very

time when all the world was hunting for materials similar to those from which the Chinese made their porcelain, we had in England some of the finest deposits of suitable clay. In Dresden, in 1710, a man riding on horseback noticed that his horse's feet were covered with a white material. Men of fashion in those days used starch for powdering their hair and he thought this material could be used instead of starch. The German chemists, however, found that the powder was kaolin, and this led to the establishment of the celebrated Dresden China Works. In France, in 1765, a lady discovered a deposit of very white clay, and as soap was expensive in those days, she suggested to her husband that it would be useful owing to its soapy nature for cleaning purposes. French chemists, however, found out its true nature, and the lady's discovery led to the foundation of the world-renowned Sèvres China factory.

Clay was also brought to this country from Virginia and a man named Cookworthy recognised that there was similar material in Cornwall, and started in 1773 the well-known pottery at Plymouth, which was afterwards removed to Bristol. There were many distinct varieties of clay—the red and yellow clays used in brickmaking; the strong clays of Poole and Devonshire, which were quite soft and plastic and could be moulded into any shape; fireclays, which withstood very high temperatures; and shales found under coal seams from which sanitary ware was made. Some shale was so hard that it required to lie out in the open for 2 years in order to become plastic. A slate quarry was nothing but a great pit of clay deposited perhaps millions of years ago, subjected to very great pressure and heat, and no longer capable of taking up water. Fuller's earth was a special sort of clay. The oil shales were also more or less clay in which oil, which had been formed by nature, had been sucked up by the shales and retained there until they were dug out, put into retorts and the oil distilled from them.

Clay played an important part in one of our great industries—the manufacture of pottery—and although we only started at a very late period, as compared with China and Japan, it was now a great industry and the high grade china and stoneware made in this country were unequalled, both for quality and artistic design. It was from the ridges of granite to be

found in Cornwall, that the china clay came and he described some of the uses of clay in paper making and the textile industries. An interesting series of lantern slides (some of which were taken with polarised light) was thrown upon the screen, including sections of quartz and feldspar, views of quarries and mines in Cornwall, and the different processes for treating the clay until it becomes the pure china clay of commerce. There was also a view of a sample of extra pure clay, lent by Mr. D. N. Laurie, with a perfect ammonite fossil form in china clay; and a diagram giving details of two bore holes at Bovey Tracey, in which there were 17 distinctly different beds of lignite and 556 feet of clay. When they remembered how long it took for an inch of clay to be deposited in a lake, they would realise the immense period of time required to form such a deposit of clay. Dr. Ormandy briefly indicated the scope of his second lecture and the meeting then adjourned.

Specimens of granite, quartz, felspar and mica were kindly lent to illustrate the lecture by the Director of the Geological Museum, Jermyn Street, S.W., and the Society and the lecturer are also indebted to the English China Clay, Ltd., of St. Austell, for the samples of china clay, china stone and other products, as well as for many photographs from which slides were made. Thanks are due to Mr. Northall Laurie for the loan of his fine coloured micro photographs.

PROCEEDINGS OF THE SOCIETY.

SIXTH ORDINARY MEETING.

WEDNESDAY, DECEMBER 7th, 1921.

H.E. THE BELGIAN AMBASSADOR in the Chair.

THE CHAIRMAN, in introducing M. Emile Cammaerts, the author of the paper, said it was a very great pleasure to him to find himself again at the Royal Society of Arts, which had many connections with Belgium. Several Fellows of the Society had given the people of Belgium proofs of their warm sympathy. There were many homes in Belgium whose inhabitants remembered with heartfelt gratitude the name of Sir Henry Trueman Wood—who was the Secretary of the Society at the beginning of the war, and was now a Vice-President and member of the Council—because, with the help of his daughter, Sir Henry succeeded in starting

and maintaining at Aldeburgh a school for young Belgian girls who had sought refuge in this country during the sad times of the war.

The paper that was to be read that evening was not the first dealing with Belgium to be read before the Royal Society of Arts. During the war, Sir William Goode, the Secretary of the National Committee for Relief in Belgium, gave the Society a remarkable account of the activities of that Committee, which, as those present would remember, collected funds for the American Commission for Relief in Belgium. Also, he had personally attended a meeting of the Society when a paper on Ypres was read by the Belgian Director of Fine Arts, M. Lambotte, at which meeting the Archbishop of Canterbury spoke. Since the war, Sir Cecil Hertslet, always a true friend to Belgium, had been able to give a vivid account of the work of reconstruction carried out in Belgium since the Armistice.

M. Cammaerts, who was going to speak on "Literature and International Relations," was well known to everyone present. He was one of the greatest Belgian poets. He had charmed many by the grace of his Muse, and during the war his patriotic strains often upheld the courage of his compatriots. Although M. Cammaerts' tastes and great talent drew him towards literature, he was also particularly competent to speak on all matters concerning the intercourse of nations, and most especially on the relations existing between Belgium and Great Britain. Thirteen years spent in a country which had become a second fatherland to him had given him experience of life in England as well as in Belgium. Being a literary man he was well qualified to speak on the subject he had chosen for his paper—which was not always the case with those who spoke about literature. The work which M. Cammaerts had accomplished had afforded him an opportunity to appreciate the immense advantages which could be derived from the development of literary intercourse between nations, and at the same time he had seen the difficulties which must be overcome in order to bring that about. He would state in his paper what, in his opinion, were the best means of doing away with the intellectual barriers between different countries. Literature would in that way serve the highest interests and the purest aspirations of international politics.

The following was the paper :—

LITERATURE AND INTERNATIONAL RELATIONS.

By EMILE CAMMAERTS,
Of the Anglo-Belgian Union.

Without attempting to prophesy, we may say that the present period will be considered, in the future, as a great period of political and intellectual transformation

comparable to that which Western Europe experienced in the 16th century. The Renaissance coincided with the creation of the centralised modern state, resting mainly on the increased power and prestige of the King, which superseded the communal and feudal units into which each country had been divided in the Middle Ages. The present transformation is somewhat different since the creation of a kind of super-state, ruling and policing all the nations of the world, seems to have been definitely discarded. The Washington Conference and the League of Nations may, nevertheless, be considered as tentative means to bring about a state of world citizenship. Such a transformation can only take place in democratic nations if the majority of the people take some interest in it, that is to say, if every citizen, besides his local and national interests, is able to exert personal influence on the course of international events. We are urged to influence, through public opinion, our respective governments, and the delegates whom we send to the Assembly of the League of Nations and to other international conferences.

This is surely a new departure. Up to 1914, the general public had only taken a secondary interest in foreign affairs, leaving the respective foreign offices and the diplomats to struggle with the difficulties as best they could. It was even assumed that foreign politics, dealing with questions in which all citizens were equally interested, stood outside ordinary political rivalry. We can only congratulate ourselves on the new outlook, but we must be prepared to face certain serious difficulties. If the old method of so-called "secret diplomacy" did not succeed in preventing international conflicts, we must not assume that the new method of open discussion will necessarily be more successful, unless some very energetic measures are taken to educate public opinion internationally, as it has been educated nationally. Certain symptoms of danger are already apparent. They may be seen, for instance, in the hasty criticism of certain decisions of the League of Nations by some of the most enthusiastic supporters of the movement. They may be seen also in the influence exerted by internal politics on some people's views of foreign affairs. Why and how one's personal opinion on home policy should affect one's view on the Silesian question, for instance, remains

a mystery, but we must, nevertheless, recognise the fact that the partisans or opponents of the government in every country are inclined, at present, to uphold or to condemn the government's foreign policy, not on its own merits but simply as a party question. If this tendency were to develop it is easy to imagine that, instead of removing the causes of friction, it would do a great deal to multiply them, and we should soon have to regret the time when foreign and internal politics worked on more or less distinct lines. It is, therefore, greatly to be hoped that some steps will be taken in every country to enlighten public opinion sufficiently to allow every citizen to consider foreign questions without prejudice. A certain amount of criticism is unavoidable, and, to a certain extent, justifiable, but it is urgent that the critic should be well-informed and should be able to realise the position occupied by the citizens of other nations with a certain amount of sympathy.

Are we, at the present time, properly equipped to prepare children and adults for their duties as world citizens? Or must we re-adjust our present means of education to the new international situation created by the war?

It will be generally admitted that the various channels through which such an education must be given are the school, the formation of certain societies, the press, and literature in general. Let us examine briefly how matters stand in these various departments of intellectual activity, and what may be done to increase their efficiency for the improvement of international relations.

It is rather the fashion to criticise education. Educationalists are faced with the very difficult problem of dealing with a wider and wider field of knowledge in the same limited amount of time. Even supposing classical studies to be entirely sacrificed, which in many ways would be greatly to be deplored, it has become scarcely possible to provide a complete modern education within the limits of school years. It is, therefore, urgent to utter a plea in favour of three branches which are essential to international education; History, Geography and Foreign Languages. It is unnecessary to insist on the value to any student of foreign affairs of a general and sound knowledge of History and Geography. We cannot open a paper without realising

how much we are handicapped by the lack of it. We cannot discuss foreign matters without realising how many educated men and women remain ignorant of facts which, in any civilised society, ought to be common knowledge. I have been asked again and again, for instance, how the Belgians could show such patriotism, considering that their nation only came into existence in 1830, and, only a few days ago, I was told by a certain clergyman that the judgment of the League of Nations was unfair because it placed a great number of Germans under Polish rule in Silesia, while no Poles were placed under German rule. The same kind of observation might be made by any Britisher travelling abroad, should any question relating to British history, like Ireland, for instance, come under discussion. Whatever curtailments are contemplated by our educationalists, the position of History and Geography in the curriculum must be maintained, and even strengthened. We might, also, perhaps, devote less time to our own country, whose principal features are bound to be impressed upon us by experience, and more to foreign countries, with which we are not naturally brought into contact.

Some people hope to solve the language difficulties by generalising the study of some universal language, such as Esperanto. Within certain limits, and for practical use, such a language may render considerable service, but, from the educational point of view, it has little value. A language is more than a vehicle of expression; it has been slowly built and transformed through centuries of evolution, and is stamped with the spirit of the people who created it. A study of French, for instance, not only allows us to talk more or less freely with the French people, and to read French books, but it teaches us, more than anything else, the genius of the French people. Every idiom is a psychological discovery and nothing brings us closer to a people's thoughts than a thorough knowledge, not only of what they say, but of the way they say it. If one might give advice in this matter, one might suggest that if less concentration is needed in history and geography, more concentration would be useful in the study of foreign languages. It is far better to know one language thoroughly than to have a smattering of three.

It is to be hoped that, in the future, every adult will deem it his duty to join some society aiming at bringing nations closer together. The League of Nations Union, with its hundred thousand members and its three hundred branches in Great Britain has started this kind of work with an enthusiasm which cannot be too much admired. Whatever the future of the League, and whatever form it may take hereafter, we trust that this great organisation will continue to develop and to further interest, not only in the League or any similar association, but in all international matters with which such an association may have to deal. It is, however, beyond the scope of the League of Nations Union to link together all the nations of the world. No single association can cope with such a tremendous task, which can only be dealt with through specialisation. A good many dual associations existed before the war, a good many more have come into existence lately. We have already in London an Anglo-French, a British-Italian, an Anglo-Swedish, an Anglo-Norwegian and Anglo-Batavian, and last, but not least, an Anglo-Belgian Union. Each of these Unions ought to bring together all those who for intellectual or economic reasons are specially interested in the two countries. Their activities ought not to be limited to the relationship between a small colony and the bulk of any particular nation; they ought to be pursued on parallel lines and simultaneously in both countries, so that all those engaged in increasing the interest in one country, in the one centre, should realise that a similar work is being undertaken, on the other side, and that for every friend they enlist for, let us say, Belgium, their fellow members are enlisting a friend for England. Our Anglo-Belgian Union has drawn great strength from this friendly rivalry, and when the idea of dual Unions is fully developed, we may imagine a net-work of such associations all over the world acting for each League of Nations Union as a kind of "agent de liaison." Such a net work, woven quite independently of any particular class or party, would be very difficult to rend. It would be the business of each Union to prevent the creation of any ill-feeling, and to check its growth, correcting mis-statements and clearing away mis-understandings as soon as they appear.

When all this educational work is accomplished, the greatest influence for evil or for good will still remain with the journalist and the writer. It is scarcely necessary to remind ourselves of the work accomplished on both sides by the press during the war. While the armies were struggling on the battlefields, an intellectual battle was waged behind the lines, attacks followed by counter attacks, accusations being disproved or confirmed. There was scarcely any writer, any professor, in the countries engaged in the war, who did not take a certain share in this work. Here, also, we were unprepared and obliged to follow the example of our enemy, and to adopt the name they were pleased to give to this activity—propaganda. It was rather an unfortunate name, because it caused, in certain quarters, the impression that news was adulterated according to the needs of each party, and that when history came to be written all this literature would become practically valueless. Some efforts have been made in this country, lately, to bring before the public certain documents issued by German propaganda in the hope that, the other side having been able to express its views, responsibilities would be more or less evenly balanced. I do not think that these efforts have been particularly successful, and that such publications, for instance, as that of the translation of the German White Book (dealing with the acts of the German Army in Belgium), are likely to alter the verdict of history. It must not be forgotten that if it was in the interest of the German propagandist to bolster up a bad case by eloquent denials and unfounded counter accusations, it was equally to the interest of Allied propaganda, since the word must be used, not to spoil a good case by anything more than the truth.

All the experience we have acquired in press matters during the war must now be devoted to the maintenance and strengthening of peace. Even among the Allied nations, differences of interest and of outlook have made their influence felt since the Armistice. Now that many questions which never reached the public are openly discussed, the press has to assume new responsibilities. I hasten to say that, in this country, almost every important journal has, up to the present, resisted the temptation to cater for sensationalism, and has given an example to the world. If there are any improvements to be suggested it

would be in the direction of better information from abroad. Foreign news reaches us, either through agencies or through correspondents. It is satisfactory to notice that certain agencies which were rather inclined to try to increase the number of their subscribers by sending unconfirmed and sometimes mischievous news, have been strongly discouraged from indulging in this practice by the discrimination of editors. On the other hand, the way in which news from the foreign press are sent to us is not yet satisfactory. Far too much is made of the opinions of extremist papers, with a small circulation, which do not represent any important fraction of public opinion, while moderate statements, from more influential quarters, are totally ignored. There is still a tendency to spread, in each country, views from abroad which are most opposed to the general trend of opinion. It may add some flavour to the reading of our evening papers, but it is neither accurate nor conducive to good understanding.

It is often discussed among journalists whether it is better for a paper to have foreign correspondents belonging to the country in which the paper appears, or to the country from which the news is sent. Whichever method is adopted, it is essential that the correspondent should have a thorough knowledge of both countries in order, on one side, to provide correct information, and, on the other, to present such information with due regard to the temperament and inclinations of the people for whom he writes. What happens frequently now-a-days is that the journalist, to whom this mission has been entrusted, vents his own special views and grievances in a foreign paper which cannot possibly share his interests, or that, if he belongs to the country for which he writes, he is inclined to strengthen the national prejudices of his readers instead of dispelling them. While an agency is mostly concerned with the accuracy of the news and the rapidity of its transmission, the correspondent's task ought to be to explain the internal difficulties which confront the country in which he resides, and the way these difficulties affect its foreign policy. To take a concrete example: both the British and the French might have obtained a fairer opinion of each other's policy if all foreign correspondents, writing for both countries, had kept in mind, on one side, the difficulties facing the Empire, and the

urgent necessity for restoring normal conditions, and, on the other, the sincere and not altogether groundless, apprehensions caused by a possible recurrence of German militarism. This task requires a good deal of tact and intellectual humility. It is difficult for any man to place himself in the situation of another. It is still more difficult for a nation to sympathise with another nation's troubles. The spirit of the crowd is inclined to wax passionate and intolerant, but if the world of to-morrow is to be built, it is not going to be built on intolerance. It might, perhaps, be a very good thing if foreign correspondents belonged neither to the country for which they write, nor to the country from which they write. Referring to the example given above, I should suggest that a well-informed Belgian correspondent might perhaps serve the interests of both countries better than anyone else for, as a Belgian, he would readily recognise British economic difficulties and French anxieties with regard to the Rhine frontier.

Even supposing our education and our press organisation better adapted to the international necessities of the future, a considerable obstacle has still to be overcome before friendly relations can really be established between the nations of the world. The most accurate information, the most moderate and sympathetic comments will not suffice to remove friction deriving from differences of temperament. We reach here the very bed-rock of our difficulties. Just as there are individual temperaments which must be realised and understood before any solid friendship can be founded, there are national temperaments which must be realised and understood before a real peace can be established, not merely a physical peace excluding the use of force, but a spiritual peace checking envy and intrigue. Behind almost every diplomatic difficulty we may discover a temperamental difficulty. Conflicts of interests are only one aspect of the question; the psychological element is far more important. We not only use different languages, but the same words convey different meanings, whether they are used in one country or another. Internationalists usually find it convenient to ignore this fundamental difficulty; they boldly declare that national temperaments determined by climate, surroundings, centuries of religious and intellectual life, do not exist, but those who have at heart

the reconciliation of mankind must not be blind to facts and shirk the greatest obstacle in their way. The tremendous influence of tradition faces us at every turn. It may be unfair, it may be misguided, but it is there, nevertheless. The example of Ireland stares us in the face at the present moment. As an extreme instance, it may be interesting to remember that in some parts of Belgium "Spaniard" is still preserved as a term of abuse.

International education will, therefore, not be complete unless a certain knowledge of foreign art and foreign literature helps us to realise our differences. Nowhere is the national temperament better expressed, nowhere can its expression be better studied and admired. It is a fact of common knowledge, that the greatest artists and the greatest writers whose genius is recognised all over the world, have been devoutly attached to their particular town, or country. There is no such thing as international art or literature, and there very likely never will be. The greatest painters, the greatest poets, can only represent what they see, or what a long tradition of ancestral knowledge leads them to think and to feel. It thus happens that the classics of modern languages, such as Dante, Shakespeare and Molière, which are studied all over the world, give us the key of Italian, British and French temperament. Quite apart from scholarly interests, the knowledge of the masterpieces of foreign literature leads us towards a higher understanding of our respective national character, and we may hope that the time will come when, instead of regretting these differences, we shall rejoice over them as so many signs of the richness and variety of human nature.

There is, in this direction, a serious obstacle to overcome—the scarcity and insufficiency of translations. It seems strange that, in our enlightened century, British people should still have to complain of having no adequate rendering of Molière's works, while, with the exception of one or two dramas, the translation of Shakespeare into French can hardly be called satisfactory. When we turn to more modern work, the intellectual gap created by the difference of language is still more noticeable. The French only began to know Ruskin shortly after his death. I did some pioneer work in this direction fifteen years ago, and was rather aghast to learn, when coming to England, that the great art prophet, who

had scarcely begun to be popular in French speaking countries, was already almost forgotten in the country of his birth.

Some people will tell you that the deficiency in translation is due to the fact that, in many cases, an adequate rendering of the original is almost impossible. We may thus attribute to extra-refinement what is merely the result of lack of organisation and neglect. If translations are inadequate, it is not because they present insuperable difficulties, but rather because all the best men who might write them with great success are engaged on more profitable work. Towards the end of the Middle Ages and the beginning of the Renaissance, almost every work of interest passed from one country to another, and the greatest writers did not think it below their dignity to devote years of labour to the creation of a new version. This intercourse was so constant, that scholars still discuss whether a romance, poem or play originated in one or the other of the Western European countries. Let me quote, among scores of others, the example of your morality play, "Everyman," and its Flemish version, "Eelckerlyk." If this work was done in centuries when it took weeks to go from one capital of Europe to the other, can it not be carried on in the age of aeroplanes, and wireless telephony? We are told that the rapidity of communication is bound to bring us more closely together, but unless this material and economic intercourse is strengthened by moral and intellectual intercourse, it is scarcely conducive to better relations.

We have reached a marvellous development from the technical point of view, but this development is not balanced by adequate intellectual intercourse, as those know only too well who endeavour to keep up with foreign literature when residing in another country. It thus happens that the most foolish prejudices which estrange one nation from another have not yet been eradicated, and they are just the prejudices which cause most harm, because they misinterpret essential characteristics of race or nation. I should think that the majority of Britishers are still persuaded that French demonstrativeness is a symptom of sentimentalism, while the majority of the French still adhere to the familiar legend according to which Britishers are typically cool and phlegmatic. Now, for anybody in the least acquainted with both literatures, it is obviously the reverse which is true. If

the French display such profuse politeness, is it not because they are stern realists? If they yielded to the temptation of expressing their views in straightforward speech, it might perhaps wreck the amenities of social life. If the British, on the other hand, seek refuge in a cold exterior, is it not, to a great extent, in order to defend themselves against their over-powering tendency to sentiment?

Since we possess different temperaments, it is high time that we should learn to interpret them correctly, and to take them into account in all manifestations of social international life. Contemporary literature is often confused and misleading. It is difficult to discern, among the celebrities of the day, those who are most likely to outlive their period, and who are specially representative of the nation. But the great classics of the last centuries remain, for the true internationalist, a tower of strength. The student will find in them the explanation and even the justification of a great many things which would otherwise hurt his feelings and undermine his hope in the future of mankind.

When all is said, the two pitfalls of international relations may be attributed, on one side, to an exaggeration of national feeling, and on the other, to a total absence of it. These two attitudes of mind are all the more dangerous as they are bound to attract both the ignorant and the impassioned. We have seen the German people so intoxicated with their own glory as to try to impose, through every means at their disposal, their rule and their culture on the world. We have seen the Russians, or, at any rate, a great number of them, so carried away by idealist nihilism as to wreck their own country and do their very best to wreck others. Instead of being an obstacle to peace, enlightened nationalism is the very condition of the establishment of friendly relations between nations. It is only through the devotion which you have for your own country that you may understand and respect the devotion other people may have for their country. It is only through the knowledge of your own limitations and weaknesses that you can acquire sufficient indulgence to recognise and to excuse similar weaknesses elsewhere. Patriotism and internationalism, properly understood, are not opposed, and the artists and the writers who have been able, through their genius, to make their national

temperament better known and better appreciated all over the world, are, perhaps, the first pioneers of a true League of Nations.

DISCUSSION.

THE CHAIRMAN (H.E. The Belgian Ambassador) said he was sure everyone present had listened to M. Cammaerts' interesting paper with the same pleasure that he had experienced himself. The author had shown that literature was, perhaps, the best means of developing and improving the relations and good feeling between the nations.

DR GEORGE MACLEAN (Director, British Division of the American University Union in Europe) said he was sure all those present had been drawn to the meeting by the name of M. Cammaerts and also by the most timely subject chosen for the paper—literature and international relations. He was a little surprised that the author elevated journalism into the field of literature, and he was the more surprised at that because he had just been reading one of the most admirable reports ever issued by a Government Committee—the Report of the Committee on the Teaching of English, of which Committee Sir Henry Newbolt was Chairman—and in that report, while due respect was paid to literature and to how English should be taught and while the report covered the whole field of education in English, even the drama, there was no reference whatever made to journalism. He hoped that the ideal view of journalism which the author had might one day be attained. The genial humour of the author appeared in the paper time and again, and he suspected that the author had been using what was known in the United States as “molasses” in place of vinegar in order to win the journalists to higher things. He had expected that the whole paper would be devoted to what the author called “general literature” literature in the highest application of the term—but he recognised the wisdom the author had shown in dealing with what the schools might accomplish and also the international agencies. Among those international agencies there was certainly none more successful than the American Commission for Relief in Belgium, the funds of which Mr. Hoover was chiefly instrumental in raising, the surplus, some 60,000,000 francs, being used by Mr. Hoover to endow permanently the Belgian Relief Fund to promote the exchange of professors and students between Belgium and America. That was in line with the practical thought that the author presented when he indicated that there was such a thing as a good side to propaganda, in spite of the prejudice against it. He thought everyone would agree that what was required was some persistent, normal relationship that could not be labelled in any sense propaganda, and that was attained in the Commission for Relief in Belgium Fund.

There were no less than seven of such foundations at present at work in the United States such as the American Scandinavian Foundation. It was very significant and full of promise for the coming international era that there were in existence those foundations and such bodies as the University Bureau of the British Empire and the American University Union in Europe, all at work to promote understanding and the common intellectual life among the nations. Still more promising was it that the students themselves, in great organisations in the Universities of the different nations upon the Continent and of the British Empire and of the United States, were forming international circles for the study of international relations. He had been informed that there were now 90 societies in 90 different Universities and Colleges in the United States under the name of International Clubs, devoting their time to the study of geography and of international questions and even literature, and holding meetings for that purpose. After all, it was literature in the supreme sense of the term as De Quincey taught it—the literature of power and not the literature of knowledge—that united nations. An illustration of that was provided by the way in which the Greeks conquered Rome, and when the Renaissance came it was Greek letters that gave it birth and rejuvenated the nations of the West. Again, taking even a rationalistic view of the Bible, what was it but the great literature of the Hebrews which had conquered the nations of the Occident? He thought literature might be defined as the embodiment in letters of the life of the soul. The author had shown the value of the soul life of each of the nations, but literature in the highest sense represented the soul of humanity, and, therefore, comparative literature was needed, not only for the sake of international relations, but that people might know the value of their individual and of their national souls and attain to a vision of the possibilities of their race. Therefore, literature would be of inestimable value in promoting the new international era. Abraham Lincoln, the backwoodsman, uttered one piece of literature that would be immortal among free peoples in his Gettysburg speech, and that piece of American literature was to-day going round the world and uniting the nations to continue the fight of freedom for peace as they fought together for victory in the war. During the summer of the present year he had been in Scandinavian countries and frequently asked the people there if they knew of any American authors whose works they read in translation or otherwise, and two or three names were frequently mentioned, such as Longfellow and Emerson. If Americans had contributed three or four to the immortals whose works were translated and read in different nations, he had hope for the future of his people. One of the secrets of the assimilation of the many elements that made up the American people was to be found in the

use of literature. There were Chairs of Comparative Literature in many Colleges in the United States and in every College there was a Professor of English Literature, which was always taught because of the glory of English Literature that was the heritage of all. A National Anthem should be literature. He thought the National Anthem of America, "My country, 'tis of thee" was literature—it was simple, but it had soul in it and appeal in it to every man who was an American. At a great American gathering there would be assembled people of all extractions, but people who had come to America because they loved it, and they would rise and sing that National Anthem, and it was also sung by the children in the schools—whether they were Russians, Jews, Bohemians, Italians, or of any other nationality.

MR. LAURENCE BINYON said he was in cordial agreement with every word of the paper. He was delighted with the singularly broad tone and the wise temper of all that the author had said, and was particularly pleased with what he had said about nationalism and internationalism. Many people held the view that the one cure for the present unfortunate state of the world from which we were trying to emerge was to destroy the sentiment of nationality, but personally he agreed most profoundly with the author's view on the subject. The sentiment of nationality could no more be destroyed than love or religion. Forces such as those had had devastating effects on human life all through history, but it was no use trying to destroy them; they must be educated, and that education could be achieved by literature. He was sure it was generally felt that ignorance was the great enemy, and he supposed that, if the war could be said to have had any good results, one of those good results was that it had taught people a great deal of history and geography and had brought many nations into contact which had had no connection with one another before that time. It must be remembered that a little learning was a dangerous thing, and there was the danger that people of different nations might only see the superficial characteristics of one another. He thought that English people, especially, were liable to dislike people of other nations for the most trivial reasons. To avoid a superficial knowledge of other nationalities it was very useful to have friends of those nationalities to whom one could talk, but as only a few people could enjoy that privilege literature should be employed instead. He thought it was most important for English people to keep in touch with what might be called the Latin tradition, the tradition which had been formed as a heritage from the great system of civilisation which was embodied in the Roman Empire. It was the great misfortune of Germany that she was never

conquered by Rome and never entered into that great system of civilisation. In the eighteenth century the relations between England and France were close and constant, and, when that intercourse ceased with the Napoleonic Wars, it seemed to him that the English people clothed themselves in an atmosphere of provincialism which was very regrettable. In conclusion, he wished to thank the author for his admirable discourse.

MR. ALAN A. CAMPBELL SWINTON, F.R.S. (Chairman of the Council), proposed a hearty vote of thanks to M. Cammaerts for his enthralling address and to His Excellency Baron Moncheur, the Belgian Ambassador, for presiding at the meeting. He was sure everyone present had listened to the paper with close attention and with great admiration, not only for the matter of it, but for the excellent way in which the author was able to address his audience in a language that was not his own.

The resolution was carried unanimously.

M. EMILE CAMMAERTS, in reply, said he wished to apologise to Dr. Maclean for having omitted any reference in the paper to the very important work of the American Committee in Brussels, and also for not having mentioned the organisation in this country which had been founded to promote friendship between Great Britain and America. He wished to thank Mr. Binyon for his charming speech. He felt that perhaps he ought to have concentrated more on literature itself in his paper, but he thought it was a mistake for a literary man to deal only with his pet subject, and in the reaction against that natural tendency he had perhaps indulged in rather uncalled for remarks on many other subjects, such as education, in which he was not so directly interested. That, however, was simply due to his eagerness to arrive at some practical proposition. The question must be tackled from one side or another, and he ought perhaps to apologise for having tried to tackle it from all sides at once.

The meeting then terminated.

THE OLD FAIENCE AND PORCELAIN INDUSTRY OF PROVENCE.

An interesting account of the history of the old Faience and Porcelain industry of Provence has lately appeared in the Nice journal, *L'Eclairteur*. According to this article the chief centres for the production of this class of china ware, were Moustiers, Marseilles and Varanges, with the adjacent village, Javernes. The first, Moustiers, in the Department of the Basses Alps, was established by the two Pierre Clerissy

(uncle and nephew) in 1686, whilst another member of the same family, A. Clerissy, set up a business at St. Jean du Dezert, near Marseilles, in 1695. It was not until some years after that another of the Clerissy family started in 1740 the manufacture of faience at Varanges, in the Department of the Var, which with its neighbour Javernes, soon became famous for the delicacy of design and workmanship of its ware.

The Moustiers china soon acquired fame, not only in France, but even in Spain. A complete dinner service was made to the order of Madame de Pompadour. About this time, taking with him some of the workers from Moustiers, the Duc d'Aranda established in Spain the well-known mark "Alcora," copied from the Moustiers ware.

Soon other distinguished craftsmen entered the field, and the amateur will recognise such names as Pol Roux (1727), Achard, Barbaroux, Berbiguier, Ferroud, Bondil, Combau and Antelmy. Ferrat, Guichard, Langier and Chaix, Mille, Pelloquin and Berge, Tion, Icart and Ferraud, Jean Vizey, Gaspard Viry, Joseph Fouque, Micaud, Gros, together with several members of the Clerissy family, may be noted as the principal artists employed for the decoration of this particular class of ware. The principal mark of the Moustiers china is the letter L, surmounted by an O, in other cases the L is followed by an O, a KL, EFB, AN, ABF, FB. Sometimes it is simply the initial of the decorator, M for Micaud; F, Fouque; T, Tion; G, Guichard; Gros, signed his whole name

The best specimens of the work of the first period, however, are abroad, whilst those of the second, distinguished by a lighter style of decoration, are still to be found in Provence. The fame of the Marseilles-ware is also due to Honoré Savy, who, possessing the secret of a green colour, was enabled to interest the future King Louis XVIII, and obtain for himself the title of "Manufacturer to Monsieur Frère du Roi," together with the right of using the Flour-de-Lis on his products.

The success of this industry stimulated others to enter the field, and in their turn, Joseph with Gaspard Robert, The Widow Perrin, Agnel and Sauze, Fanquier, Jean B. Viry, Bonnefoi, Boyer, Leroy set up works of their own and rendered celebrated the mark of Marseilles.

The initials A.C., either crossed or separate, are the mark of A. Clerissy, who established the art at Marseilles. Savy, who succeeded him, used a Flour-de-lis, in three different forms. Joseph Gaspard Robert used three different marks, sometimes the letter R alone, at others with a dot above, or a dot on each side.

Bonnefoi used a B, Leroy an L, Madame Perrin, the initials V.P. (Veuve Perrin) either surmounted by a star, without a star or between two dots.

Certain articles of Marseilles bear in some cases, a flower, a large comma coloured green,

blue, black or red, which must not be mistaken for the mark of Chiodo of Savona (Italy.)

Although Varages did not enter into competition with either Moustiers or Marseilles, until considerably later, that is to say about 1746, its products acquired a certain renown. Its principal establishments were those of Fabre-Bayol, Richelin, Grosdidier, Montagnac, Laurent and Guigou. The mark is a small cross in black, or A-N.

THE COMMERCIAL SITUATION IN CHINA.

Reviewing a recent report by Mr H. H. Fox, C.M.G., Commercial Counsellor, H.M. Legation, Peking, on the commercial situation in China, the *Board of Trade Journal* of November 3rd says:—

A recent tour of the northern provinces served to strengthen the opinion held for some time past that China, in spite of internal dissensions and misgovernment, in spite of lack of communications and neglect of the scientific development of her vast natural resources, is making slow but real progress, and that she is on the eve of a period of unexampled commercial and industrial development which will in a few years' time bring about a complete change in her economic situation. The potential wealth of the country is enormous: China is producing in steadily increasing quantities almost every kind of raw material—animal, vegetable and mineral—known to the world's industries; she is beginning to utilise these materials by manufacturing for herself what she has in the past been obliged to import from abroad. The standard of living all over the country is rising slowly among the mass of the people, very quickly among the educated moneyed classes. The Chinese have overcome to a large extent their traditional dislike and suspicion of foreigners and foreign ways, and are rapidly assimilating Western customs and Western modes of living. Foreign style goods are ceasing to be luxuries and becoming necessities, and Mr Fox believes that this tendency is to our advantage, and that we shall see that the Chinese, while relying more and more on their own industries to supply the wants that intercourse with foreign nations has created, will purchase far more freely than they have done in the past the better class of goods that they cannot produce at home. And in the process of this industrial development there will be a demand for every description of foreign machinery and mechanical appliances which should keep British manufacturers busy for many years to come. No marked increase of business in any line can be looked for until there is some improvement in economic conditions throughout the world, but there are grounds

for hoping that for China, at any rate, the worst times have passed: there is a distinct revival in the export trade following on enquiries from Europe and America for China produce, and this has led, as was generally predicted, to the Chinese coming forward and taking delivery of the gradually dwindling local stocks of piece-goods and other commodities, thus clearing the way for new business. It is to be hoped that the disastrous results that followed on the reckless over-trading of 1920 will have taught both foreigners and Chinese a lesson that they will not soon forget, and that buyers and sellers will henceforth conduct their business on less speculative and sounder lines than they, many of them, have done in the past.

Mr. Fox's Report (with Appendices) can be obtained from H.M. Stationery Office, Kingsway, London, W.C. 2.

OBITUARY.

ARTHUR WALKER.—Intimation has been received of the death of Mr Arthur Walker, of Whitehaven, who was elected a Life Fellow of the Royal Society of Arts, in 1919. After being educated privately in this country, he was sent to the Moravian School at Neuwied, and he subsequently studied in French Switzerland. He then returned to England and entered the tannery at Whitehaven. In conjunction with his friend, Mr. W. J. Ingle, he investigated the possibilities of many new raw materials and tropical products, and was very successful in opening up fresh business with the colonies.

In 1913, he became a director of the Whitehaven Colliery Company, Limited, and devoted much time to the study of mining problems. He frequently went down the pits, and became extremely popular with the colliers.

GENERAL NOTES.

AMERICAN TRADE COMPETITION IN INDIA.—H.M. Senior Trade Commissioner in Calcutta, Mr. T. M. Ainscough, reports that one of the few trades in which the United Kingdom is not entirely regaining its pre-war position in India appears to be that of boots and shoes. Last year America shipped to India £432,200 worth of boots and shoes, as compared with £596,000 from this country. Before the war practically the whole of these articles came from the United Kingdom. The general opinion of a number of importers in India as to the reason for the lack of recovery of British trade in this particular line seems, Mr. Ainscough writes, to be that during the war, the impossibility of obtaining supplies from home compelled the importers to buy elsewhere, and naturally the repeat orders

will for some time retard the restoration of British trade. American prices are now considerably higher than British—upon the average 33s. 6d. against 16s.—and it seems quite probable that in the near future the main bulk of the trade will return to us "provided that adequate supplies at reasonable prices are obtainable."

"THE PRACTICAL ENGINEER" SCHOLARSHIP.—The Proprietors of *The Practical Engineer* have decided to award a Scholarship in Mechanical Engineering to the value of £30 9s. to a subscriber of *The Practical Engineer* who shall be adjudged the most suitable candidate. The course comprises a thorough treatment of mathematics, applied mechanics, drawing, steam power and machine design, supplemented by a complete treatise on modern engineering shop practice. It is intended for machinists, toolmakers, pattern makers, foundrymen, blacksmiths, apprentices, draughtsmen, designers, foremen and superintendents. The subjects are treated with special reference to the needs of those engaged, or intending to engage, in machine shop and foundry work and in drawing and designing machinery. Further particulars may be obtained from the Editor, *The Practical Engineer*, 8, Brooms Buildings, Chancery Lane, London, E.C. 4.

MODERN INDUSTRIAL ART IN THE VICTORIA AND ALBERT MUSEUM.—The British Institute of Industrial Art is opening an Exhibition of Present Day Industrial Art, to be held, with the sanction of the President of the Board of Education, in the North Court of the Victoria and Albert Museum, from the 16th January to the 25th February, inclusive. The endeavour of the organisers is to bring to the notice of the public the latest productions of both manufacturers and craftsmen. The exhibits are chosen by expert Selection Committees in the various divisions, and consist of the following main sections:—Textiles, Metalwork, Ceramics, Printing and allied industries, and Furniture, the last named being displayed as a series of rooms. On the termination of this Exhibition on the 25th February, the collections will be sent for further exhibition to Bradford, Birmingham, and other important industrial centres. Admission is free, the hours of opening being 10 a.m. to 5 p.m. on weekdays and 2.30 to 5 p.m. on Sundays.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Monday evenings, at 8 p.m.:—

JANUARY 18.—**JULIAN S. HUXLEY, M.A.**, Fellow of New College, Oxford, "Recent Advances in the Determination of Sex in Animals." **Peter Chalmers Mitchell, C.B.E., M.A., D.Sc., LL.D., F.R.S.**, Secretary of

the Zoological Society of London, in the chair.

JANUARY 25.—HOWARD MAURICE EDMUNDS, "Photo-Sculpture." ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, in the chair.

FEBRUARY 1.—ARTHUR WILCOCK, "Surface Printing by Rollers in the Wallpaper, Cretonne and other Textile Industries."

FEBRUARY 8.—EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "Some Solved and Unsolved Problems in Gas Works Chemistry." SIR ARTHUR DUCKHAM, K.C.B., M.Inst.C.E., in the chair.

FEBRUARY 15.—CLOUDESLEY BRERETON, M.A., Divisional Inspector to the London County Council (Modern Languages), "The Necessity of Speech Training, and the Need of a National Conservatoire."

FEBRUARY 22.—ALEXANDER SCOTT, Sc.D., D.Sc., M.A., F.R.S., "The Restoration and Preservation of Objects at the British Museum."

MARCH 1.—EMANUEL MOOR "The Duplex-Coupler Piano."

MARCH 8.—W. A. APPLETON, C.B.E., Secretary to the General Federation of Trade Unions, "The Proper Functions of Trade Unions." JOHN MURRAY, M.P., in the chair.

MARCH 15.—OSWALD T. FALK, "Certain Aspects of the Problem of Exchange Stabilisation." SIR ROBERT M. KINDERSLEY, K.B.E., in the chair.

MARCH 22.—PRINCIPAL A. P. LAURIE, M.A., D.Sc., F.R.S.E., "The Permanency of Oil Colours."

MARCH 29.—SIR THOMAS OLIVER, LL.D., D.Sc., M.D., F.R.C.P., "Alcohol in Relation to Industrial Hygiene." (Shaw Lecture.)

APRIL 5.—JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry." SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the chair.

APRIL 26.—PROFESSOR ERNEST R. MATTHEWS, "Sea Encroachment and its Prevention."

Dates to be hereafter announced :—

LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

PHILIP SCHIDROWITZ, Ph.D., F.C.S., "Recent Developments in India Rubber Manufacture."

MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock.

JANUARY 27.—ALEXANDER L. HOWARD, "The Timbers of India and Burma." THE RIGHT HON. F. S. MONTAGU, M.P., Secretary of State for India, in the chair.

MARCH 24.—PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India."

APRIL 28.—F. G. ROYAL-DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the chair.

MAY 26.—PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow, Magdalene College, Cambridge. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced :—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoon, at 4.30 o'clock.

MARCH 7.—MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E., "Tanganyika Territory (formerly German East Africa)." Date to be hereafter announced—

LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, C.B.E., K.C.M.G., "Queensland."

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETING.)

Friday afternoon, at 4.30 o'clock.

FEBRUARY 24. PROFESSOR WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S., "Brown Coals and Lignites: Their Importance to the Empire."

CANTOR LECTURES.

Monday evenings, at 8 o'clock.

C. AINSWORTH MITCHELL, M.A., F.I.C., "Inks." Three Lectures.

Syllabus.

LECTURE I.—JANUARY 23.—Historical Introduction—Nature of Inks—Egyptian and Chinese Inks—Modern Carbon Inks—Sepia—Iron Gall

Writing Inks—Methods of Preparation—Properties—Iron Tannates.

LECTURE II.—JANUARY 30.—Logwood Inks—Vanadium Inks—Aniline Inks—Coloured Writing Inks—Examination of Writing Inks—Characteristics of Ink in Writing—Copying Inks.

LECTURE III.—FEBRUARY 6.—Marking Inks—Printing Inks—Preparation of Lamp Black—Carbon Blacks—Boiled Oils—Typing Ink—Inks for Miscellaneous Purposes—Secret Writing.

ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., late Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington, "The Mechanical Design of Scientific Instruments." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 20.—Design from the point of view of the User and the Manufacturer—Clerk Maxwell's axioms of Instrument Design—Degrees of Freedom and Constraint—The Six Degrees of Freedom of a Rigid Body—Geometric Design.

LECTURE II.—FEBRUARY 27.—The Lower and Higher Pairs—Restraint against Sliding—Restraint against Rotation—Centroids and Axodes—The Design of Profiles.

LECTURE III.—MARCH 6.—The Elastic Nature of all Materials—The Elastic Constants—The Rigidity of Instruments—Manufacture—Models—Interchangeable Manufacture.

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester. "The Constituents of Essential Oils." Three Lectures. March 20, 27, April 3.

COBB LECTURES.

Monday evenings, at 8 o'clock.

F. F. RENWICK, F.I.C., F.C.S., A.C.G.I., "Modern Aspects of Photography." Three Lectures. May 1, 8, 15.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, JANUARY 16.. Geographical Society, Kensington Gore, S.W., 5 p.m. Mr. O. J. S. Crawford, "The Archaeology of the Ordnance Survey Maps."

Chemical Industry, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. Messrs. E. H. Richards and G. C. Sawyer, "Further Experiments with Activated Sludge."

TUESDAY, JANUARY 17.. Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m. Mr. H. W. Macrosty, "Some Current Financial Problems."

Metals, Institute of, Chamber of Commerce, New Street, Birmingham, 7.30 p.m. Prof. C. A. Edwards, "The Influence of Time and Temperature on the Properties of Alloys."

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Dr. H. S. Stannus, "Demonstration of Arts and Crafts from Nyassaland."

Photographic Society, 35, Russell Square, W.C. 7 p.m. Mr. H. V. Lawley, "Automatic Methods of Kinetograph Film Processing."

Royal Institution, Albemarle Street, W., 8 p.m. Dr. F. H. A. Marshall, "Physiology as Applied to Agriculture." (Lecture I.)

WEDNESDAY, JANUARY 18.. British Academy, at the Royal Society, Burlington House, Piccadilly W., 4.30 p.m. Monsieur Maurice Dounay, "Molière."

Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Dr. C. W. Saleeby, "The Influence of Light and Air in the Prevention and Cure of Tuberculosis."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. R. Young, "Use and Abuse of Combines and Trusts."

Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Meteorological Society, 40, Cromwell Road, S.W., 7.30 p.m. Annual General Meeting.

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m. Professorial Lecture.

Photographic Society, 35, Russell Square, W.C., 8 p.m. Mr. W. Stoneman, "Faces, Famous, Fair, and Funny."

Microscopical Society, 20, Hanover Square, W., 8 p.m. Presidential Address by Professor J. Kyre, "Microscopy and Oyster Culture."

United Service Institution, Whitehall, S.W., 3 p.m. Colonel Commandant G. A. Weir, "Some Reflections on the Cavalry Campaign in Palestine."

Constructive Birth Control and Racial Progress, Society for, Essex Hall, Strand, W.C., 8.30 p.m. Earl Russell, "Divorce and Birth Control."

THURSDAY, JANUARY 19.. Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Brig. Gen. R. K. Bagnall-Wild, "Acroplane Installation."

Chromatics, International College of, Caxton Hall, Westminster, S.W., 8 p.m. Miss Louie Bagley, "Painters of Pictures in Sound."

Linnean Society, Burlington House, Piccadilly, W., 5 p.m. 1. Dr. E. M. Delf, "Studies in *Macrocystis pyrifera*, the Giant Alga of the Southern Temperate Zones." 2. Mr. J. L. C. Musters, "The Flora of Jan Mayen Island."

Royal Institution, Albemarle Street, W., 3 p.m. Mr. S. Gordon, "Mountain Birds of Scotland, Sea Birds and Seals." (Lecture I.)

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

FRIDAY, JANUARY 20.. Transport, Institute of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Mr. G. T. Hedge, "The Operation of an Important Railway Goods Terminal."

Metals, Institute of, The University, Sheffield, 7.30 p.m. Messrs. F. C. Robinson and H. G. Dail, "An Investigation of Some Defects in Silver-plating Anodes."

Royal Institution, Albemarle Street, W., 9 p.m. Sir James Dewar, "Soap Films and Molecular Forces."

Victoria and Albert Museum, South Kensington, S.W., 2.30 p.m. Mr. A. F. Kendrick, "English Medieval Embroideries."

Engineers, Junior Institution of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. L. Turner, "Geology in relation to Engineering."

University of London, King's College, Strand, W.C., 5 p.m. Prof. R. Robinson, "Orientation and Configuration in Organic Chemistry from the Standpoint of the Theories of Partial Valency and of Latent Polarity of Atoms." (Lecture I.)

Municipal and County Engineers, Institution of, Plymouth, Conference.

Geologists Association, University College, Gower Street, W.C., 7.30 p.m. Mr. S. Hasseldine, "Classifications of the Palaeocene Age."

Mechanical Engineers, Institution of, Storey's Gate, S.W., 6 p.m. Messrs. H. S. Denny and N. V. S. Knibbs, "Some Observations on a Producer-Gas Power Plant."

SATURDAY, JANUARY 21.. Royal Institution, Albemarle Street, W. 3 p.m. Prof. C. Macpherson, "The Evolution of Organ Music." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,609

VOL. LXX.

FRIDAY, JANUARY 20, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 23rd, at 8 p.m.
(Cantor Lecture). C. AINSWORTH MITCHELL,
M.A., F.I.C., "Inks." (Lecture I.)

WEDNESDAY, JANUARY 25th, at 8 p.m.
(Ordinary meeting.) CAPTAIN HOWARD
MAURICE EDMUNDS, M.C., A.M.I.C.E.,
"Photo-Sculpture." ALAN A. CAMPBELL
SWINTON, F.R.S., Chairman of the Council
in the chair. (The paper will be illustrated
with cinematograph views.)

FRIDAY, JANUARY 27th, at 4.30 p.m.
(Indian Section.) ALEXANDER L. HOWARD,
"The Timbers of India and Burma." THE
RIGHT HON. E. S. MONTAGU, M.P., Secretary
of State for India, in the chair.

Further particulars of the Society's
meetings will be found at the end of this
number

COUNCIL.

The Council at their last meeting elected
Mr. P. M. Evans, M.A., LL.D., a member
of the Council and Vice-President of the
Society in place of the Hon. Richard Clere
Parsons, M.A., who has been compelled to
resign on the grounds of ill-health.

MANN JUVENILE LECTURES.

The second Juvenile Lecture of the course
on Clay, given under the Dr. Mann Trust,
was delivered by Mr. William Reginald
Ormandy, D.Sc., F.I.C., F.C.S., on Wednes-
day afternoon, January 11th. Mr. Alan
A. Campbell Swinton, F.R.S. (Chairman of
the Council) presided on the occasion.

Dr. Ormandy said that last week he dealt
with the origin of clay and its characteristics,
and how its colour varied—in Cornwall
being white, in Devonshire yellow, in parts
of the Thames Valley red, whilst near

London it was quite yellow, owing to the
clay becoming mixed with chalk. That
afternoon he proposed to tell them some-
thing about the properties of clay, and
what was done with it, and he was, therefore,
bound to introduce a little chemistry. Clay
was a combination of silica and alumina.
Most sands had a good deal of silica in them
which stood fine and high temperatures.
An ordinary flame was hardly sufficient
to melt it, but skilled glass blowers by the
aid of oxy-hydrogen blow-pipes formed
it into tubes. Dr. Ormandy illustrated
the difference in behaviour between a glass
tube and one made of quartz. After being
heated in a gas flame and plunged into
water the glass tube fell into powder,
whilst the quartz tube remained quite
intact. Manufacturers, he said, were using
quartz vessels as they resisted acids, and
chemical apparatus was also being made of
quartz because of its property of withstand-
ing a great amount of heat and sudden
cooling without cracking. He spoke of
the formation of a quartz crystal and ex-
plained how it was composed of atoms or
molecules arranged like the steps in a spiral
staircase. He then dealt with alumina
(from which aluminium was made) and
showed that there were metals which would
burn in water, metal sodium and potassium
being experimented with. He mentioned
that in his student days the price of
aluminium foil was 10s. an ounce, whereas
at the present time blocks of aluminium
could be had at the rate of 1s. per lb. The
foil, he said, was covered with a micro-
scopically thin layer of oxide of alumina,
which was obtainable from clay. He
pointed out the risk of using a strong soda
in cleaning aluminium utensils, and illus-
trated the action of caustic soda, and water
containing a minute quantity of corrosive
sublimite, in completely destroying some
aluminium foil, although he said, ordinary
washing soda or carbonate of soda would

not do them very much harm. He also gave an illustration of the effect of brushing corrosive sublimate upon a sheet of aluminium foil and how the action continued for a long while after the mercury solution had been washed off. A demonstration was also given to show that aluminium would burn, and he stated that aluminium powder mixed with iron oxide forms the metallic iron used for repairing broken tramway lines.

Some interesting experiments were then shewn of the peculiar property clay has of absorbing coloured materials. Clay was added to two solutions of pink and blue, the colours of which were rapidly taken up by the china clay. This, he said, was the principle upon which the coloured crayons of commerce were made. Alumina was also used in the manufacture of the beautiful tints known as lake colours. Porous plates (i.e., plates which has not been glazed) were used in connection with these experiments to receive the coloured clay deposits, and these plates were used by chemists who required something to absorb liquids rapidly; they were also largely used in making electric batteries and appliances in the manufacture of dyes. He referred to the manufacture of hand-made and wire-cut bricks and hand-moulded crucibles, and also described the methods employed in making semi-dry bricks, and glazed tiles, which were compressed clay dust burnt in the kilns to the biscuit form. He also illustrated the action of an electrolyte containing silicate of soda upon a quantity of fairly thick clay, rendering it quite thin, and showed how clay could be deposited electrically like silver and copper by means of electro-osmosis treatment. The water split up the electrolyte into electrified particles, and every little particle of clay took upon its surface one or more charged particles--they ran away from one pole and collected on another. This principle had been utilised for the purification of clay. It was impossible to pour ordinary thick clay into a mould, but by using moulds of plaster of Paris, which sucked up the moisture in the thin clay, they were able to make clay crucibles no thicker than a sheet of writing paper. Teacups, vases, etc., were moulded in the same manner and at a much cheaper rate than was possible by other methods. Crucibles were now being produced in England (which in the course of manufacture, had undergone temperatures

ranging from $1,500^{\circ}$ to $1,540^{\circ}$ C) which were not only equal to but better than anything that had been made in Germany.

Through the kindness of Messrs. Doulton and Co., Ltd., of the Lambeth Pottery, London, to whom the Society and the lecturer are greatly indebted, a demonstration was then given of the use of the potter's wheel for throwing various forms of pottery. Dr. Ormandy said he wished to express his grateful thanks to the many people who had helped him with the lectures, including English China Clays, Ltd., of St. Austell, for all their specimens and for the numerous photographs from which many of his slides were taken; and to the Osmosis Company, Ltd., 36, Victoria Street, S.W., for the loan of apparatus. He also wished to thank Mr. D. Northall-Laurie for his beautiful coloured photographs and expressed his indebtedness to Mr. E. C. Craven, for all the help he had rendered him. He thought they should also pay tribute to Dr. Mann who had bequeathed a sum of money to the Society for the delivery of lectures on scientific subjects to children; a teacher gifted with imagination, he said, could make Science very attractive and lead them into the land of the fairy books.

The Chairman proposed a hearty vote of thanks to Dr. W. R. Ormandy, for his excellent lectures, which was seconded by Sir Herbert Jackson, K.B.E., F.R.S. This was acknowledged by Dr. Ormandy and the meeting then concluded.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

WEDNESDAY, DECEMBER 14TH, 1921.

MR. EDWARD DENT, Vice-President of the Society, in the Chair.

TRADE WITH THE NETHERLANDS EAST INDIES.

By SIR WALTER BEAUPRE TOWNLEY,
K.C.M.G., Minister to the Netherlands,
1917-19.

In order fully to realise the importance of the field for commercial enterprise which we are going to study to-night, it will, I think, be well to first call your attention to the vast dimensions of the Netherland Indian Archipelago, which has a total

area of about 738,000 square miles, and which, if we superimpose it upon the map of Europe, will stretch from the south of Ireland to the east of the Black Sea. Borneo occupies a position about relative to that of the old pre-war German Empire. The curiously shaped Celebes cover a considerable portion of the old Austro-Hungarian Empire, lesser islands are dotted over Roumania and Southern Russia, until finally we come to Dutch New Guinea, which blots out a large part of South-Eastern Russia beyond Odessa. Of this important group of islands Java and Madura, although not the largest in size, have an area of 51,960 square miles and are much the most important from an economic point of view. Out of a gross population of between forty-five and fifty millions, which it is roughly estimated inhabit the entire archipelago, somewhere about thirty-six millions are dwellers in the islands of Java and Madura, which are further much more highly developed than their sister islands.

There is a deal of romance attaching to the early history of the commercial development of the archipelago, when Spaniards, Portuguese, British and Dutch, the great sea-faring nations of the sixteenth and seventeenth centuries, disputed for the trade of the Spice Islands, but the time at my disposal to-night will not permit me to take you through the history of those stirring days which saw the birth of the British East India Trading Company and of the Dutch East India Company within two years of each other in 1600 and 1602.

Except to a comparatively small number of people the trade opening offered by the Netherland Indies was practically unknown until the wants created by the Great War called attention to the fact that these little-known islands could supply many articles of prime importance, such as rubber, sugar, tea, coffee, tobacco, mineral oils, quinine, copra, etc., whilst the spices of the Moluccas, which attracted the venturesome traders of the sixteenth and seventeenth centuries, still have a ready sale, though, of course, an insignificant one compared with some of the products just named.

Very special attention has been paid to the development of the agricultural resources of the Netherland Indian Archipelago. In many cases the colonial administration

has assisted to the utmost in the selection and introduction of the various tropical species best suited to the soil and climate of the islands, the products of which may be classified under two heads, what are known as European cultivations and native grown crops. Amongst the former are sugar, coffee, rubber, tea, tobacco, cinchona bark, cocoa and fibres, whilst, in addition to some of the above, rice, coconuts, corn, cassava and peanuts are cultivated by native agriculturists.

Sugar. The cultivation of the sugar cane has greatly developed during the last 25 years; it is entirely confined to Java, and it is claimed that it is now, thanks to untiring systematic scientific research and instruction, the most up-to-date in the world. The area under cultivation has increased 117% in the last 25 years, and the total production of sugar has increased 235% since 1894. It is interesting to note the different directions Java sugar has taken during the last years. In 1874 about 37% went to Holland, the inferior qualities going to England and Asia. From 1895 to 1902 the greater part of the production went to the United States, and from the latter date up to 1914 to East Asia and Australia. During the war years, 1915 up to and including 1917, Europe (chiefly England) and British India, bought the biggest part of the first runnings, but in 1918 China and Japan again became the chief buyers.

Coffee. Various sorts of coffee have been experimented with until experience has proved the Robusta coffee imported from Africa to be the best suited to climatic and other conditions, so that it is now rapidly superseding all other varieties. The production of coffee amounted to 807,290 piculs in 1920, and it is estimated that this year's crop will give a gross total of 985,118 piculs. These estimates anticipate a falling off in the production of all varieties but Robusta.

Rubber. The cultivation of rubber in the Netherland East Indies is of comparatively recent date, but none of the other cultivated products can show such rapid progress. The plantings consist chiefly of *Hevea Brasiliensis*, which was introduced into Java from the Amazon region in 1876. There are now some 800,000 acres under cultivation on, roughly, 680 estates, of which some 400 are in Java and the remainder in the outlying possessions. Before

the war, the export of this product was chiefly to England and Holland, but during the war years, the United States became more and more the important buyer.

Tea. There are about 220,000 acres under tea cultivation on some 300 estates, of which all but about 30 are in Java, but the cultivation of the plant is being rapidly developed in other islands, and more especially in Sumatra, where it appears to prosper well. In consequence of the unsatisfactory results obtained from the tea seed imported from Assam, the Government decided to establish official tea seed control stations at Tandjong Priok and Belawan Deli. It is claimed that much good has resulted from the measure. Like rubber, and most of the other colonial products tea has been passing through difficult times, but there is every reason to anticipate that these will prove to be only temporary set backs due to the abnormal conditions prevailing as an aftermath of the war. British Netherland Indian tea growers complain bitterly of the 21. import tax levied in the United Kingdom on all teas other than of British origin. It is claimed that a very large number of the growers are British subjects, and that the tax produces a sum to the Exchequer so insignificant as to be out of all proportion to the irritation it causes, and which may at any time produce unfortunate results. The hostility to the tax seems to be shared by all those who are interested in the tea trade, even by those who are supposed to benefit from it. Efforts to get the tax repealed have failed, but it is to be hoped that its failure to produce any good result may bring about its demise.

Tobacco. The cultivation of tobacco is carried on in Java, both by estates and by the natives, whereas in Sumatra it is entirely cultivated in plantations. Experimental stations for the purpose of giving scientific instruction in the cultivation of tobacco have been established at various places, another instance of the endeavour of the colonial administration to develop on sound lines a product likely to be profitable. Sumatra tobacco is in especial demand and is greatly used as outside wrappers for Havannah cigars. The export of tobacco increased considerably up to 1913, but fell off greatly during the years of war consequent upon the difficulty experienced in the transport trade with Holland, the chief importer both for home consumption and

for re-export to Cuba. During the war the U.S., Australia, British India, France and other countries came forward as buyers, but not in sufficient strength to compensate for the loss of the Dutch market.

Coconuts. The plantation cultivation of coconuts has increased during recent years, but compared with the native cultivation, is of small importance. The great demand for vegetable fats has caused renewed interest to be taken in this product. It is said that there were sixty-three million trees in Java and Madoora in 1917, of which over thirty-seven million were fruit bearing, and 44 millions in the other islands, of which 23 million were productive. It is estimated that the product of copra from these trees amounted to almost 368,000 tons in Java and Madura, and to 213,000 tons in the other islands. A large proportion of this was consumed by the natives themselves. Since 1917, the number of copra producing factories has considerably increased, as has the producing capacity per factory, thanks to the use of improved machinery. The factories are now said to be quite modern in their installation, and to be up to the best European and American standards. At the end of 1919, the vegetable oil industry required sufficient raw material for the manufacture of 200,000 tons of copra, apart of course, from that required for native consumption.

Cinchona. This product is very often called Peruvian Bark, a name which of itself shows that we are not dealing with a natural indigenous product of the islands. As its name implies, the cinchona tree, from the bark of which quinine is derived, is a native of South America. It was not imported in any quantity into Java until the year 1854, but the soil and climate of the island proved so suitable for its cultivation, that an almost complete monopoly of production has now been established. Java now supplies about 95% of the world's production of cinchona bark and its derivative, quinine, whilst the export from Peru is almost negligible. This result has, of course, not been reached without diligent work on the part of Government instructors and of the planters. The result of untiring experiments and skilful crossing of various species has shown that this particular plant can be more successfully grown in Java than anywhere else in the world, including India and Ceylon. In the two last named countries, cinchona cultiva-

tion has given way to tea plantation, presumably because the latter was the more profitable. Efforts are being made to re-establish the cultivation in India and Assam, but even if successful, some years must elapse before the new plantations can come to fruition.

Rice, which is the staple food of the native population, forms the chief crop of native agriculture. The production is enormous, but yet does not, at the present moment, suffice for the demand; consequently, the export of rice is forbidden, but formerly about 50,000 tons of the superior sorts were exported. Although for this reason rice does not properly enter into our calculations, still, no review of Netherland Indian produce would be complete without some reference to the rice crop, seeing that the harvest of 1919 produced about 7 million tons of padi, equal to about $3\frac{1}{2}$ million tons of hulled rice. This crop was produced on about $3\frac{1}{2}$ million hectares, of which 3 million were irrigated.

Fibres, Indian Corn or Maize, Cassava, from which the various forms of tapioca are derived, and *Pepper*, both black and white, are further important articles of export.

The *Oilpalm* is the last cultivated product which need detain us to-night. The latest reports to hand show that the cultivation of the Oilpalm in the Island of Sumatra is increasing on the East Coast and in Acheen, and that efforts are also being made to introduce this cultivation into Java. At the beginning of 1921, there were 12 plantations of about 3,000 hectares actually producing (9,000 hectares have been planted), and the output amounted to 1,719 tons. It is further shewn that exports of palm oil in 1920 amounted to 360 tons, as compared with 180 tons in the preceding year. Holland and Belgium are the chief countries of destination, and more than half the plantations are the property of Belgians and Frenchmen. These figures are small, but it is said that the oil palms flourish well, and when one thinks of what happened in the case of cinchona, one asks oneself whether a somewhat similar development in the cultivation of a tree of such exceptional commercial importance may not occur, without, of course, anticipating that the cultivation of the oil palm in the Dutch East Indies will in any way imperil the future of the oil palm in other countries. So far, the oil palm would appear to have

been planted almost exclusively in Sumatra, where the labour question must always be a hindrance to production.

The *Mining Industry* has not made very great headway in the Netherland Indies, although there is reason to believe that a fairly rich future lies open to it. Petroleum and its derivatives are exported in very large quantities, and further oil fields are being continually sought for and exploited. The Anglo-Dutch Petroleum Co. and its affiliated branches have the almost entire monopoly of the industry. The only other mineral product that is at present exported in considerable quantities is tin, which is found in the Islands of Banka and Billiton. There are three coal mines worked by the Government, but the output, which is increasing rapidly, is, so far, consumed in the islands or is used for bunkering purposes, and there is a demand for imported coal.

Business in all the tropical products has suffered severely from the abnormal conditions which have prevailed since the signature of peace. Enormous stocks had been held up in the ports during the war, owing to the shortage of shipping facilities, and as soon as possible they were rushed to the European and American markets, which, having been deprived of them for so long, were in dire need of them and accepted them at abnormal prices. Large fortunes were quickly made, both during this period and while the war lasted, and the jubilant planter thought that the era of unlimited prosperity had dawned at last. The dream, however, was short-lived, and soon the glutting of the buying markets synchronised with the inevitable shrinkage of purchasing capacity due to the financial requirements of all countries to meet the war drainage. The result was that very large unsaleable stocks remained on hand, with the natural resulting fall in prices, which has spelt something like ruin to many. It is probable, however, that in the case of many articles, the present prices are still higher than the pre-war price, though perhaps not sufficiently so to meet the increased cost of production due to higher wages and other causes.

We have seen that the Netherland Indies export many valuable products in varying quantities. Let us now examine briefly what are their requirements which British trade is in a position to supply. There is a large and steady demand for textiles of all sorts, as well as for cement, iron and

steel manufactures, beds, boots and shoes, hats, glassware, earthenware, matches, fancy goods, metals, drugs and chemicals, motor cars, food stuffs, tinned milks, mineral waters, coal, artificial manures, dyes, etc., as can well be imagined when we remind ourselves that we are catering for a population approaching 50 millions, of which many are in affluent circumstances, although, of course, the great majority are of the poorer class with small wants.

Textiles. Taking a 1,000 kilo unit, we find that the total volume of cotton yarns, bleached and unbleached, cotton piece goods, printed or dyed, including manufactured articles such as Sarongs, etc., woollens, half woollens, silk and half silk imported, amounted to 26,283 tons in 1918 and to 43,029 tons in 1920. The value of these imports was respectively 84,340,000 guilders, and 250,407,000 guilders. Great Britain and Japan are the chief exporters of cotton goods to the Netherland Indies in almost equal shares, but Holland also figures as a large exporter with articles which are, for the most part, of English manufacture, a considerable proportion of the British export trade passing through Amsterdam houses. The figures of import values given above are for Java and Madura only, and for the other islands cotton goods to the value of 17,866,000 guilders were imported in 1918, and to the value of 56,710,000 guilders in 1920. The Japanese are very keen competitors for this market, but from the latest information received, it would appear that British goods are decidedly more appreciated by the native population, who are the principal buyers, and that the market is heavily overstocked with Japanese goods for which there is an insufficient demand.

Iron and Steel Manufactures for railway construction, harbour works, irrigation works and all manner of engineering undertakings, are in great demand, and will continue to be so if all the Government Works which are announced in the budget are to be carried out. Independently of these undertakings, there is a large demand for all descriptions of mechanical plant for private concerns. The 1922 Budget is noticeable for its very wide programme of building construction. In accordance with the habitual policy of the colonial administration, it is probable that the contracts for these works will be given almost exclusively to firms established in the islands, but it should be noted that large quantities of

building materials will have to be imported.

The statistics for 1919, showing the import to the Netherland East Indies of machines, machinery, machine tools, and all mechanical devices allied to the machinery industry, together with hand tools and agricultural tools, give us a grand total in value of fl53,938,424. Of these goods, to the value of fl20,000,000 were imported from Holland, fl19,000,000 from the U.S.A., about fl10,000,000 from the U.K. and dependencies, and the remainder from various sources, of which the most important were Japan, Australia, Sweden, Switzerland, France and Denmark in the order named. During the first nine months of 1921, the total import of iron and steel manufactures amounted to 737,329 metric tons; of this Great Britain's share was only 71,021 tons, whereas the amount sent direct from Germany during that period was 194,013 tons. Holland supplied 231,486 tons, of which, no doubt, a considerable portion was of German origin, who before the war supplied almost all the tools and implements required for mining and agricultural purposes. The reason for this was largely because German firms held big stocks in spare parts.

Please do not imagine for one moment that the absence of Germany's name from the list of countries I have just read to you implies that she has withdrawn from the market. Quite the contrary is the case. In addition to the customary suppliers before the war, the renowned Hugo Stinnes, who has become to finance and commerce of to-day almost what the bogey-man is to children, has turned his attention to this vast market, which is susceptible of so great development. Thanks to his driving power, a very powerful combine, known as the Rhine-Elbe Union, has been formed, which seems determined, if possible, to capture the entire trade in hardware, if not in other things; also, through the instrumentality of the well-known firm of Carl Schlieper, probably the most powerful distributing agency in the archipelago. The Allgemeine Electricit ts Gesellschaft has been added to the combination, which shows that the Germans are also alive to the possibilities, which are enormous, of the development of electrical power and appliances. The Germans have already secured for themselves a very sound position, as they have entered into an arrangement with the colonial administration, which

has been severely criticised in the Second Chamber of the States General at The Hague, under which, in return for most valuable orders for railway material of all sorts, they have undertaken to establish a factory at Cheribon for the manufacture of iron and steel plant.

This factory will probably prove to be little more than an assemblage works in which parts imported from Germany will be put together, but it will undoubtedly benefit by the favoured treatment which is accorded to industrial undertakings established in the islands. In addition, the German organization has set up large and important offices, on a scale to impress the native with their country's trade position, at Bandoeng, where there is a staff of technical engineers of high standing always on the look out for first news of anything that may come along.

I have not time to-night to go more fully into all the trade openings that offer themselves in this market, but I would call your special attention to the motor industry which has, so far, been greatly neglected, apparently in the belief that the market is already overstocked with cheap American cars. My latest information is to the effect that this is not, in fact, the case, although there are large numbers of such cars, which appear to be almost unsaleable. The truth seems to be that the American car has lost its popularity to no small extent, whilst there is a good demand for the too little known British car. I am not going to trouble you so late in the evening with a list of comparative prices of American and English cars, but I have satisfied myself that some of our new low-priced, but reliably built cars, can very well hold their own—and more—in price with the American variety on the market, and that further, the higher priced and more luxurious car would find ready purchasers among the richer classes. *But*, and this is a big one, the British car, to be a success, must be accompanied with the necessary arrangements for procuring spare parts on the spot. The native buyer will not put his money down for a car unless he can be sure that, in the event of anything going wrong, he can rely upon obtaining the necessary spare part without having to wait weeks or months for it to come from England.

Shipping. No paper dealing with the trade of such a far distant market as this one would be complete without some

reference to shipping and harbour facilities. In this connection, it is pleasing to note that the 1922 Budget contains provision for the improvement of the existing ports, and for rendering others more accessible for ocean steamers. It is true that in the past, and I might add up to the present, the ports of the Netherland East Indies were badly equipped to cope with sea-borne traffic. There are those who hold that the four million pounds sterling allotted to harbour works in the 1922 Budget are insufficient for the objects in view, but one must remember that in these days money is not readily come by, and we must hope that these four millions are an earnest of better things to come in the future. The shipping facilities are regular and good, and are being added to, while new ports of call in the islands have been established during the past years, greatly to the advantage of certain districts.

Finances. On the occasion of the Queen's birthday, on the 31st of August last, the Governor General stated that the finances of the country were not critical or dangerous, but, nevertheless, required constant care. This very non-committal statement did not carry the student of the financial situation very far, more especially as the speech was delivered just after a loan of 75 million florins had been successfully floated. The Budget which was issued after a further hundred million State loan had failed of success, bears a rather less optimistic complexion, but on the whole, the situation would not appear to be unfavourable. There has certainly been some rather extravagant administrative financial legislation, founded apparently upon the belief that was generally shared that the high prices after the war had come to stay, but, in the opinion of reliable financial authorities, the burden of debt is not excessive, and no fiscal measures should be needful of a nature to drive away the enterprising spirit of the Dutchman and the foreigner.

Taxation is relatively heavy, and has sometimes been carried out without sufficient regard to the legitimate needs of those who have assisted in the development of the prosperity of the islands, but recent experience has shown that a willing ear is lent to reasonable representations on this head.

I hesitate to abuse the honour done me by the Society of Arts in asking me to read

this paper to you to-night by anything in the nature of propaganda, even for a public institution of such importance as the British Chamber of Commerce for the Island Countries under review, but I have been obliged to cut out much detail, and would only say that anyone who would like to have fuller information upon any point will be welcome at the Offices of the Chamber, where we shall, moreover, have much pleasure in enrolling him as a member.

DISCUSSION.

THE CHAIRMAN, in opening the discussion, said the paper showed how many openings there were for British industry in the Netherlands East Indies, and the sooner they were taken advantage of the better; otherwise the Germans, who had already started their operations there, would extend them still further. One product which had not been mentioned by the author, and which was used a good deal now, was kapok. It grew in Java and Borneo, and was used in life saving apparatus instead of cork. In former days there had been a book entitled "Java, or How to Manage a Colony," which had always been looked upon as a standard work in those days. Java, then, had paid a large annual sum to Holland, her surplus revenue being very much more than her expenditure. Now, he believed, it was the other way about. Java had such a large population that her coolies went all over the place. In Borneo they helped to cultivate the rubber there. He agreed with the author that the production of China tea was now dying out; only a very little of the best quality was grown. A large amount used to be made for the Russian market, but now that market was dead, and therefore every year less and less came to this country. He also agreed with the author in regard to the extra 2d. duty which was levied on Netherlands East Indies and foreign tea. It seemed a very small matter and had only been put on during the war to satisfy some people, and he thought it would be taken off in a very short time. Cinchona had been planted in Ceylon, because coffee had at first proved a failure there, and had taken some time to develop, and the planters had grown cinchona as a go-between. Now that tea paid better, the production of cinchona was dying out.

MR. F. C. STROOP thanked the author for the excellent bird's-eye view he had given of the Dutch Indies. Of course, in the space of one hour Sir Walter could not give anything else but a bird's-eye view of the subject; yet he thought the statements made in the paper were quite sufficient to rouse an interest in the

minds of those who were not well acquainted with Java and would lead them to a further study of the matter. Java was certainly a most wonderful country. He had not himself been there since 1891, when there were 25,000,000 inhabitants. The last official figure is 36,000,000, which is an immense increase. To show what a remarkable island it is, he might mention that he travelled all through Java, and in one place it had been difficult for his conveyance to find its way through the population. There is a province called Bagelen where the density of the population is greater than in Belgium, which is the most thickly populated country in Europe. That gave a slight idea of the importance of Java. It was not only that the soil in Java is exceedingly fertile and that there is generally water to be had both in the natural way and by irrigation, but Java had at the same time what so many other countries lacked, namely, a very large and very industrious population to help to cultivate the soil. The author had said very little about the other islands comprising the Dutch East Indies. He (the speaker) was a Dutchman by birth, but had lived nearly 50 years in England. He had always remained true to the country of his birth as well as to that of his adoption. He felt no jealousy whatever that the author should take such an active interest, through his Chamber of Commerce, in the Netherlands East Indies, and should draw the attention of British traders to the possibilities of Java, because Holland was such a very small country as compared with her colonies in the East Indies that she could not possibly hope to do justice to all that is to be done there, and welcomed the introduction of foreign capital and enterprise.

MR. J. M. FRASER said there was very little he could add to the points made in the paper. Of course, in a paper like that which Sir Walter had presented that evening it was not easy to condense the whole volume of trade which it would be possible for Great Britain to do with Java. There were great possibilities in Java, and the audience had heard what the Germans were doing there; but he feared that British manufacturers did not quite realise that it was absolutely necessary to combine and concentrate their whole attention on re-gaining that market. There was a great deal of unemployment in this country at the present time, which, he was afraid, was due to the fact of not having had the right people in Java and on the Continent to represent the British firms. He was largely interested in sugar mills in Java. Up to about 20 years ago the British manufacturer had the monopoly of the machinery for the sugar mills. Then a German manufacturer had sent out a very enterprising commercial traveller. The representative of the British firms was a very nice

gentleman, but he only spoke English. The German representative spoke Dutch, and ingratiated himself with the managers of the sugar mills. On one occasion one of the mills required some new machinery. An offer was received from two British manufacturers quoted in sterling f.o.b. Southampton. On the other hand a slightly cheaper offer was received from the German manufacturer and from another German firm quoted in gilders, delivered at the factory, with a plan of the factory showing how the machinery was going to be put up. Unless British traders would adopt those same methods, he did not think they would beat the Germans. The fact must be emphasised to British traders that the men they sent out as commercial travellers to the Colonies and elsewhere must be men that know the conditions of the country they were going to, and who were able to speak the language; and also British manufacturers must help their men by being willing to take the risk of the exchange and of the freights, and to quote in the currency of the country to which their goods were going.

MR. DAVID LLOAD HOWARD remarked that he had listened with the very greatest interest to the paper, and more so because, as far as the general trade of Java was concerned, he had no personal knowledge whatever. His own experience had been confined solely to the question of Cinchona bark. That product had an intensely interesting history, but it would take up far too much time for him to endeavour to give even a sketch of it at that late hour of the evening. Suffice it to say that quinine, which was made only from Cinchona bark, was one of the most necessary medicines in the treatment of one or more of the various diseases which were known as malaria, and consequently it had played a very important part in the war. The author, who was then Minister at the Hague, knew very well one side of the importance of quinine in the war. He, as a manufacturer of quinine under the orders of the British Government knew the other side, and he only wished he could tell the story; it was a very interesting one. In the latter days of the war, especially when fighting was going on in the Strumitza Valley and also on the Piave Front, which were two of the most pestilential neighbourhoods in the world, quinine became of enormous importance, because it was so obvious that when a man was down with fever it was no use providing him with munitions or anything of that sort; his fever had to be cured first before he could handle a rifle or manipulate a gun. The cultivation of Cinchona in Java gave a very good instance of the wonderful Dutch thoroughness and foresight. It had been a combination of good luck and good judgment—of good luck because among the larger mountains there, there were stretches of soil which were of exactly the right quality, and at the right height, and with the

right conditions. The Cinchona Tree was very fastidious, although it could be grown under very various circumstances. For instance, as a little boy he saw it growing in a green-house in Tottenham. But to grow it satisfactorily one had to have exactly the right soil and the right climate. The Dutch were lucky in having the right soil, but it had not been all plain sailing. In the early days they had got hold of a lot of seed which resulted in a very poor type indeed of Cinchona. They had not been content with that, but had looked around and had found better seed. They stubbed up thousands of acres of plantations of the poor stuff and replanted them all with the better stuff, the result being whereas a very fine natural bark from South America would perhaps test 5½ per cent. of quinine sulphate, in the year before the war the average of the whole crop of Cinchona Bark of Java touched 6½ per cent., and he had himself tested samples of Dutch Bark showing 11 per cent. or slightly over.

MR. H. J. DE JONG said he merely desired to make one or two remarks with regard to the exportation from England of goods not only to the Dutch East Indies but to all foreign markets not having English measurements and the English monetary system. He was a Dutchman carrying on business in England—largely an export business, and he found it essential always to quote in kilos. Further, he always made it a point of quoting in particular foreign currency whenever possible. By so doing he had found that he had got trade which firms not willing to follow his example did not get. Another point which British firms overlooked was that the buyer abroad liked to be written to, if possible, in his own language. He had found that some foreign buyers were especially sensitive on that point. For instance, if one wrote to a Spaniard in French because one did not know Spanish, the odds were that the Spaniard was offended; he would rather be written to in English. If Britain would only adopt the decimal system both in coinage and in measurement he thought her trade would benefit largely thereby.

MR. F. B. S'JACOB (Dutch Commercial Secretary) thought the whole subject had been so well covered by the author's admirable address that it was almost impossible for him to add anything useful. He might say fiscally the Dutch Indies East and the Mother Country were now entirely separated. That had not been the case, as the chairman had said, about 50 years ago, but for a long time there had been one Budget for the Netherlands East Indies and another for the Netherlands, and they had nothing to do with each other. Another point he would like to make clear was that the Netherlands East Indies had long adopted the policy of the open door. There were no differential

duties as between goods from Holland or goods from England or any other country, and it was rather a sore point with Dutchmen that in England certain articles produced in Netherlands East Indies were being differentiated against—such as tea and sugar. If those differential duties which had given rise to so much complaint could be done away with in this country, there was no doubt about it that it would be very highly appreciated in Holland and in the Dutch East Indies. He thanked the author for the kind references he had made to the Dutch nation and Government, and could assure him that every Englishman who went to the Dutch East Indies was always an extremely welcome arrival. The more they got the better they liked it, because they had always found in the Dutch East Indies that the Englishman made an extremely desirable colonist, and not a little of the prosperity of the trade of the islands was due to the British firms which had been established there.

MR. W. M. J. WILLIAMS said he had been very much interested in what the author had said about the effect of the preference duty on tea and sugar, and matters of that kind, and he trusted that Sir Walter would use his well-known influence to get that altered. He was quite sure that the people of this country got a very indifferent benefit from that duty. If tea cost 10d. in Assam, then tea coming from Java would cost 1½ according to our law, but the consumer of tea in England did not get that benefit; the difference between the 10d. and 1½ evaporated somewhere else. In the long run, especially at the present time when we wanted more trade, it would be very desirable to see such distinctions blotted out of our tariff.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his paper.

SIR WALTER TOWNLEY, in reply, thanked the audience for their kind reception of his paper. The remark made by one of the speakers about the use of languages brought to his mind the fact that some complaints had reached him of the fact that English firms sometimes wrote to the Netherlands Indies in German, and in very bad German too, and such a thing was not liked there.

NOTES ON BOOKS.

A HANDBOOK OF THE BARODA LIBRARY DEPARTMENT. By Newton M. Dutt, Curator of Libraries, Baroda, and Reader to H.H. the Maharaja Gaekwar. Baroda : Central Library, 1921.

In 1909, a series of papers on "The Manufactures of Greater Britain"—the term "Over-seas Dominions and Possessions" had not then

come into general use—was read before the Royal Society of Arts. One of these valuable papers dealt with industrial India, and the Chairman on the occasion was the Maharaja Gaekwar of Baroda. In the admirable speech he delivered His Highness urged that the "greatest want in India" was education, a want that he has endeavoured to supply so far as his own State is concerned, by bestowing upon it the boon of free and compulsory instruction. The splendid Library Department he has since established as one of the fruits of his frequent travels in the Western world, is further evidence of his zeal in the cause of education and self-culture. He obtained from America the services of an able expert, who was engaged for three years in planning and organising the institution described by Mr. Dutt in his handbook. The department includes a fine central library in the capital of the State, aided libraries and reading rooms in a very large number of *mofussil* (country) towns and villages, travelling libraries, a "visual instruction section," which, by means of the cinematograph, lantern slides, etc., caters specially for the non-literate, and training classes for librarians. Another interesting feature is the use that is made of the valuable Sanskrit manuscripts, which have been collected throughout India for the Central Library, namely, the periodical issue of the *Gaekwad's Oriental Series*. Already eighteen volumes have been published, and have gained high praise from scholars like Sir George Grierson, Superintendent of the Linguistic Survey of India, Dr. A. A. Macdonell, Boden Professor of Sanskrit at Oxford, and Dr. F. W. Thomas, Librarian, India Office. On the shelves of the Central Library are some 89,000 volumes, in addition to 18,000 books set apart for the travelling library. The nucleus of the main collection was formed by the Maharaja Gaekwar's gift of his own private library, consisting of about 20,000 volumes. At present, the Central Library, with the administrative offices, is accommodated in what was formerly the residence of the Maharajas. A new building has been decided upon, the plans of which are being prepared by Sir Edwin L. Lutyens, R.A. Even before the establishment of the Library Department, Baroda was fortunate in possessing an excellent free library, which was founded by His Highness's brother, Shrimant Sampatrao Gaekwad, who for many years has been a Fellow of the Royal Society of Arts.

A COAL MANUAL FOR SALESMEN, BUYERS AND USERS. By F. R. Wadleigh. Cincinnati : National Coal Mining News. In cloth \$2.50 : in leather, \$3.50.

This handbook is designed to meet the needs of salesmen and users of coal. The author describes the various uses of coal and the ways in which it is classified. The principal coal-

fields of the world are next taken, and a list is given of the estimated coal reserves of the principal coal producing countries of the world. The United States head this list with the enormous total of 3,534,554,000,000 tons. The methods of purchasing, sampling and analysing coal are discussed, and special chapters are devoted to anthracite, coke, and boilers and furnaces. The final chapter deals with the question of storage and that mysterious phenomenon, spontaneous combustion. How much is known about it may be gathered from this remark of Mr. Wadleigh's: "We can only say that while each kind of bituminous coal has been stored without spontaneous combustion, yet spontaneous combustion has taken place with every kind of coal." Coals of uniform size, free from dust or slack, are generally free from liability to spontaneous combustion, while a mixture of different sizes is more liable to fire than coals of similar size.

The causes leading to spontaneous combustion have never been satisfactorily explained. An interesting article on the subject appeared in this *Journal* on June 26th, 1919, when the author, the late Professor Watson Smith, wrote: "So-called 'spontaneous combustion' arises by reason of such chemical and physical changes in bodies mostly consisting of, or containing carbon (carbonaceous substances), and under the influence of atmospheric oxygen, that sufficient heat is generated to give rise ultimately to combustion." He cites a great many cases in which "spontaneous combustion" has occurred in coal and other substances, and he shows that it has been the cause of great loss of life and of property, both on land and sea.

Interesting as the subject is, however, this is hardly the place to discuss it. Mr. Wadleigh naturally only gives it so much attention as is in proportion to the size of his book, but he gives a list of rules for storing coal which, as he says, "summarise the best practice." They are drawn up by Professor H. H. Stock and Mr. W. D. Langtry, President of the Commercial Testing Company of Chicago, and if they are carefully followed they will do much to ensure safety against this mysterious source of danger.

The handbook contains a great deal of information of much value to all who use coal; while the bibliography at the end of the volume will enable those who so desire to study the subject in greater detail.

COAL TARS AND THEIR DERIVATIVES. By Dr. G. Malatesta. London: E. and F. N. Spon, Ltd. 1920. 21/- net.

Here we have a book of 330 + XII large octavo pages, with 180 illustrations. It is translated from the Italian, by a translator whose name does not appear, but the title page informs us that it embodies revisions, corrections, and additions by the author.

The notable and characteristic merit of Dr. Malatesta's work in its original Italian form, is the full and exact delineation of notable tar and tar-products' plants, and the exactness of the descriptions. The drawings, many of which show remarkably full details, are reprinted in the translated version now before us, and we may especially refer to page 141 on which is a highly complex drawing illustrating the plant for the Coppée method of condensing and separating the tar products which are generated in the manufacture of furnace coke: the details being further elucidated by the figures on the two following pages. As part of the sequence of these drawings there are about fifty descriptive words or sentences, but all these are the original Italian. As the understanding of the drawings depends largely on these words or sentences, it seems remarkable that English expressions were not substituted, as we may take it that some readers— and possibly many— may be troubled by the absence of translation.

Further we must say that we are not fully satisfied with the translation of the general text as it appears to have been made by one not having a very thorough knowledge of the delicacies of the English usages and idiom, or possibly the final reading at the office of the publishers may have been somewhat hurried.

"Like a house on fire" (p. 3) is not a very happy literary simile for rapid industrial progress. "Recovered" (3rd line from end, p. 37) does not quite correspond to the English sense and moreover the sentence in which it is used, rather suggests Italian in English words than well reading English: further, the description of ash-determination (p. 508) may embarrass many readers, or even be wholly unintelligible to some.

Dr. Malatesta's work has many merits, one being the numerous references to sources and authorities; but English chemists who revere the memory of our pioneer workers would rather see a mention of Greville Williams in connection with picoline, than the suggestion of two personalities as embodied in the expression "Greville and Williams" (pp. 276 and name index).

OIL SHALES. By H. B. Cronshaw, B.A., Ph.D., A.R.S.M. London: John Murray. 5s. net.

In this monograph, which forms one of the series produced under the direction of the Mineral Resources Committee of the Imperial Institute, the author first describes oil shale and the similar material torbanite; the mining and distillation of oil shale, and the composition and properties of oil shale. He next deals with deposits of oil shale and torbanite in various parts of the British Empire, including those in the Utrecht district of Natal, Wakkerstroom district of the Transvaal, Albert County in

New Brunswick, Pictou County in Nova Scotia, Blue Mountains in New South Wales and Mersey district in Tasmania. Accounts of foreign deposits are given, and include those of the United States, France, Bulgaria and Brazil. A map showing the oil shale deposits of the world, and a bibliography conclude the volume.

GENERAL NOTES

THE INSTITUTION OF ELECTRICAL ENGINEERS: COMMEMORATION MEETING—For the purpose of commemorating the first meeting of the Society of Telegraph Engineers, which was held on the 28th February, 1872, the Council of the Institution of Electrical Engineers (originally the Society of Telegraph Engineers) are arranging for the following Institution Meetings to be held on dates approximately corresponding to that of the original meeting:—*Tuesday, 21st February, at 4 p.m.* Popular Lecture (admission by ticket, a limited number of seats being reserved for guests) by Professor J. A. Fleming, F.R.S., on "Michael Faraday and the Foundations of Electrical Engineering." *Tuesday, 21st February, at 7 p.m. (for 7.30 p.m.)* Annual Dinner at the Hotel Cecil. *Wednesday, 22nd February, at 8.30 p.m.* Professor Fleming will repeat his Lecture of the previous day. *Thursday, 23rd February, from 4 to 6 p.m., and from 8 to 10 p.m.* A number of members of the Institution and others closely connected with the early development of Electrical Engineering will give short discourses on their reminiscences and experiences during the early history of the Electricity Supply Industry. The speakers will deal both with matters of scientific and technical interest and also with the effect of legislative action on the progress of the industry.

OIL SEED PRODUCTION IN INDIA—In normal years, writes the United States Trade Commissioner in India, that country produces some 5,000,000 tons of oil seeds, worth about £50,000,000, one-third of which is usually exported. No other country produces such a variety, which includes cotton seed, rape seed, peanuts, sesame seed, mowra seed, poppy seed, niger seed, linseed, castor seed, as well as copra. Linseed, niger seed, and poppy seed were formerly used in paints and varnishes as liquid drying oils, and rape seed was employed for industrial purposes, but linseed and rape seed can be refined for the production of margarine, and much rape seed is being used for this purpose on the Continent of Europe. Copra and mowra yield solid fats, while liquid non-drying oils are expressed from cotton, sesame, rape, and castor seed, and from peanuts. India furnishes 98 per cent. of the castor seed of the world, the oil from which is considered the best lubricant for aeroplane engines, and also supplies 100 per cent. of the mowra, 100 per cent. of the

niger, 65 per cent. of the rape, and 76 per cent. of the poppy seeds of the world.

PHYSICS AND CHEMISTRY OF COLLOIDS.—A report of a discussion on the above, held jointly by the Faraday Society and the Physical Society of London, in 1920, has been published by the Department of Scientific and Industrial Research, on account of the exceptional scientific and industrial importance of the questions discussed. The contents include an Introduction, consisting of the papers, "A Short Survey of the Physics and Chemistry of Colloids," by Professor The Svedberg, and "The General Structure of Colloids," by Dr. Wolfgang Pauli, and papers and discussions under the following headings:—Section 1—Emulsions and Emulsification. Section 2—The Physical Properties of Elastic Gels. Section 3—Glass and Pyrosols. Section 4—Non-Aqueous Colloidal Systems. Section 5—Precipitation of Disperse Systems. Section 6—Electric Endosmosis and Cataphoresis. Two appendices are also included, No. I, "The Proteins and Colloid Chemistry," by Jacques Loeb, and No. II, "On the Internal Pressure of Liquids," by H. Kuecbone Tompkins. Many of the leading European authorities on this subject contributed to the proceedings of the conference.

THE WOOLLEN INDUSTRY OF JAPAN—The Japanese woollen industry is still virtually in its infancy, its growth having been greatly hindered by war conditions, which made it practically impossible for the requisite material to be secured. Substantial encouragement for development is, however, being given by the Japanese Government. The Government itself is a very large owner of the various kinds of machinery used in the manufacture of woollen goods, and this machinery is being loaned out, at a nominal charge, to private undertakings engaged in or taking up the industry. A further measure of help is in the form of exemption from taxation—every new woollen manufacturing enterprise being free from taxation during the period of its first two years' operation.

AEROPLANES AS SCARECROWS—In order to prevent the great damage done by ducks on the Californian rice fields, an aeroplane patrol was established to fly over the fields and scare away the birds. This system was started in 1919, and was so successful, according to *California Fish and Game*, that now five aeroplanes are kept busy, making both day and night flights to frighten off the wild ducks. But while the farmers are highly pleased, the American Game Protection Association is greatly perturbed on account of the number of birds killed by striking the propellers and guy ropes, and it has demanded that the permits for the use of aeroplanes for this purpose should be revoked.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 p.m. :—

JANUARY 25.—HOWARD MAURICE EDMUNDS, "Photo-Sculpture." ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, in the chair.

FEBRUARY 1.—ARTHUR WILCOCK, "Surface Printing by Rollers in the Wallpaper, Cretonne and other Textile Industries." SIR CECIL HARCOURT SMITH, C.V.O., LL.D., Director of the Victoria and Albert Museum, in the chair.

FEBRUARY 8.—EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company, "Some Solved and Unsolved Problems in Gas Works Chemistry." SIR ARTHUR DUCKHAM, K.C.B., M.Inst.C.E., in the chair.

FEBRUARY 15.—CLOUDESLEY BRERETON, M.A., Divisional Inspector to the London County Council (Modern Languages), "The Necessity of Speech Training, and the Need of a National Conservatoire." SIR HENRY NEWBOLT, C.H., D.Litt., LL.D., Chairman of the Departmental Committee on the Teaching of English, in the chair.

FEBRUARY 22.—ALEXANDER SCOTT, Sc.D., D.Sc., M.A., F.R.S., "The Restoration and Preservation of Objects at the British Museum."

MARCH 1.—EMANUEL MOOR, "The Duplex-Coupler Pianoforte."

MARCH 8.—W. A. APPLETON, C.B.E., Secretary to the General Federation of Trade Unions, "The Proper Functions of Trade Unions." JOHN MURRAY, M.P., in the chair.

MARCH 15.—OSWALD T. FALK, "Certain Aspects of the Problem of Exchange Stabilisation." SIR ROBERT M. KINDERSLEY, K.B.E., in the chair.

MARCH 22.—PRINCIPAL A. P. LAURIE, M.A., D.Sc., F.R.S.E., "The Permanency of Oil Colours." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., in the chair.

MARCH 29.—SIR THOMAS OLIVER, LL.D., D.Sc., M.D., F.R.C.P., "Alcohol in Relation to Industrial Hygiene." (Shaw Lecture.)

APRIL 5.—PROFESSOR ERNEST R. MATTHEWS, "Sea Encroachment and its Prevention."

APRIL 26.—JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry." SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the chair.

Dates to be hereafter announced :—

LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

PHILIP SCHIDROWITZ, Ph.D., F.C.S., "Recent Developments in India Rubber Manufacture."

MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock.

JANUARY 27.—ALEXANDER L. HOWARD, "The Timbers of India and Burma." THE RIGHT HON. E. S. MONTAGU, M.P., Secretary of State for India, in the chair.

MARCH 24.—PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India."

APRIL 28.—F. G. ROYAL-DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the chair.

MAY 26.—PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow, Magdalene College, Cambridge. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced :—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoon, at 4.30 o'clock.

MARCH 7.—MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E., "Tanganyika Territory (formerly German East Africa)." Date to be hereafter announced :—

LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, C.B.E., K.C.M.G., "New Zealand."

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETING.)

Friday afternoon, at 4.30 o'clock.

FEBRUARY 24.—PROFESSOR WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S.,

"Brown Coals and Lignites: Their Importance to the Empire."

CANTOR LECTURES.

Monday evenings, at 8 o'clock.

C. AINSWORTH MITCHELL, M.A., F.I.C.,
"Inks." Three Lectures.

Syllabus.

LECTURE I.—JANUARY 23.—Historical Introduction—Nature of Inks—Egyptian and Chinese Inks—Modern Carbon Inks—Sepia—Iron Gall Writing Inks—Methods of Preparation—Properties—Iron Tannates.

LECTURE II.—JANUARY 30—Logwood Inks—Vanadium Inks—Aniline Inks—Coloured Writing Inks—Examination of Writing Inks—Characteristics of Ink in Writing—Copying Inks.

LECTURE III.—FEBRUARY 6.—Marking Inks—Printing Inks—Preparation of Lamp Black—Carbon Blacks—Boiled Oils—Typing Ink—Inks for Miscellaneous Purposes—Secret Writing.

ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., late Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington, "The Mechanical Design of Scientific Instruments." Three Lectures. February 20, 27 and March 6.

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester. "The Constituents of Essential Oils." Three Lectures. March 20, 27, April 3.

COBB LECTURES.

Monday evenings, at 8 o'clock.

F. F. RENWICK, F.I.C., F.C.S., A.C.G.I., "Modern Aspects of Photography." Three Lectures. May 1, 8, 15.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, JANUARY 23.—British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Prof. W. Rothenstein, "Architectural Draughtsmanship."
East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Mr. H. E. A. Cotton, "Castes and Customs in Malabar."
Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 7 p.m. (Graduates' Meeting). Mr. F. A. Best, "Airships."
Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Mr. S. T. Klein, "The Invisible is the Real, the Visible is only its Shadow."
Geographical Society, 135, New Bond Street, W., Mr. E. J. Edmonds, "Luristan."
Royal Dublin Society, Leinster House, Dublin, 4.15 p.m. Dr. H. H. Poole, "Some Notes on the Distribution of Activity in Radium Therapy under different conditions of Screening."

TUESDAY, JANUARY 24.—Civil Engineers, Institution of, Great George Street, S.W., 6 p.m. 1. Mr. A. W. Rebdell, "Control of trains, in relation to increased weight and speed combined with reduced headway." 2. Sir Henry Fowler and Mr. H. N. Gresley, "Trials in connection with the Application of the Vacuum-Brake for Long Freight Trains."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. C. M. Thomas, "The Plate and the Photographer."

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, Piccadilly, W., 4.30 p.m. Mr. G. Collingwood, "Hadrian's Wall: a History of the Problem."

Anthropological Institute, 50, Great Russell Street, W.C., 8 p.m. Anniversary Meeting. Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Rev. Dr. G. E. Lloyd, "British Emigration and the Future for Western Canada."

Royal Institution, Albemarle Street, W., 3 p.m. Dr. F. A. H. Marshall, "Physiology as Applied to Agriculture." (Lecture II.)

WEDNESDAY, JANUARY 25.—Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Mr. A. C. Inman, "Laboratory Aids to the Diagnosis of Tuberculosis Infection."

Oriental Studies, School of, Finsbury Circus, E.C., 12 o'clock Miss Alice Werner, "Bantu Mythology and Folk Lore." (Lecture I.) 5 p.m. Mr. A. Sabonadire, "Some Cases I have Tried."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. F. Hughes, "Conditions of Industrial Harmony."

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5 p.m. Marquis of Crewe, "Some Writers on English Country Life."

United Service Institution, Whitehall, S.W., 3 p.m. Major-General W. H. Anderson, "The Crossing of the Canal du Nord by the First Army."

University of London, University College, Gower Street, W.C., 5 p.m. Mr. H. G. Spenning, "The Palace of Minos."

Civil Engineers, Institution of, 9, George Street, S.W., 6 p.m. (Students' Meeting). Mr. W. E. Monkhouse, "The Economic Aspects of Various Methods of Power-Transmission."

THURSDAY, JANUARY 26.—African Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m.

Microscopical Society, 20, Hanover Square, W. 7.30 p.m. (Metallurgical Section). Mr. H. Wrighton, Demonstrations of Polishing Metal Specimens.

Mechanical Engineers, Institution of (Midland Branch), The University, Birmingham, 7.30 p.m. Mr. J. D. Morgan, "High Tension Spark Ignition in Internal Combustion Engines." (North-Western Branch) Memorial Hall, Albert Square, Manchester, 7 p.m.

Royal Society, Burlington House, Piccadilly, W., 4 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Concrete Institute, 296, Vauxhall Bridge Road, S.W., 7.30 p.m. Mr. E. B. Moullin, "Capillary Canals in Concrete and the Percolation of Water through them."

Royal Institution, Albemarle Street, W., 3 p.m. Mr. Seton Gordon, "Sea Birds and Seals." (Lecture II.)

FRIDAY, JANUARY 27.—Royal Institution, Albemarle Street, W., 9 p.m. Viscount Burnham, "Journalism."

Engineers, Junior Institution of, 39, Victoria Street, S.W., 8 p.m. Mr. L. M. Jockel, "Fuels and the Boiler House."

Physical Society, Imperial College of Science, South Kensington, 5 p.m.

SATURDAY, JANUARY 28.—Royal Institution, Albemarle Street, W., 3 p.m. Dr. C. Macpherson, "The Evolution of Organ Music." (Lecture II.)

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday of the week preceding the Meeting.

*For Meetings of the ROYAL SOCIETY OF ARTS, see page 173.

Journal of the Royal Society of Arts.

No. 3.610.

VOL. LXX.

FRIDAY, JANUARY 27, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 30th, at 8 p.m.
(Cantor Lecture). C. AINSWORTH MITCHELL,
M.A., F.I.C., "Inks." (Lecture II.)

WEDNESDAY, FEBRUARY 1st, at 8 p.m.
(Ordinary Meeting.) ARTHUR WILCOCK,
"Surface Printing by Rollers in the Cotton
Industry: A comparison with other Pro-
cesses of Printing Patterns for Cretonne,
Dress Materials, Wall Papers, etc." SIR
CECIL HARCOURT SMITH, C.V.O., LL.D.,
Director and Secretary, Victoria and Albert
Museum, in the chair.

DOMINIONS AND COLONIES SECTION.

A meeting of the Dominions and Colonies
Section Committee was held on Monday,
January 16th.

Present:—Major Sir Humphrey Leggett,
D.S.O., R.E., in the chair; Mr. A. H.
Ashbolt (Agent-General for Tasmania); Hon.
Sir James Daniel Connolly (Agent-General
for Western Australia); Sir Charles H. T.
Metcalf, Bt., Mr. F. C. Wade, K.C. (Agent-
General for British Columbia); and Mr.
George Wilson, C.B., with Mr. G. K. Menzies,
M.A. (Secretary of the Society) and Mr. S.
Digby, C.I.E. (Secretary of the Dominions
and Colonies and Indian Sections).

PROCEEDINGS OF THE SOCIETY.

EIGHTH ORDINARY MEETING

WEDNESDAY, JANUARY 18th, 1922.

PETER CHALMERS MITCHELL, C.B.E., M.A.,
D.Sc., LL.D., F.R.S., Secretary of the
Zoological Society of London, in the chair.

The following candidates were proposed
for election as Fellows of the Society:—

Ainsworth, E., London.

Anderson, Roy King, Bassein, Lower Burma.

Ashworth, Sidney Herbert, A.I.Mech.E., V.D.,
Naihati, Bengal, India.

Bando, S. N., B.Sc., Calcutta, India.

Brooks, Milton, Calcutta, India.

Yabsley, Percy, Aylesford, Kent.

The following candidates were balloted
for and duly elected Fellows of the Society:—
Hopkins, James Love, LL.B., St. Louis, U.S.A.
Ruddick, James, Quebec, Canada

The CHAIRMAN, in introducing the lecturer,
said that he was the grandson of Thomas Henry
Huxley, one of the greatest figures in the
history of British biology: that he had volun-
tarily resigned a professorial chair in the
United States, and returned to serve his country
with distinction during the war, and that, by
his investigations at Oxford, he was rapidly
gaining a reputation as one of the rising younger
men of science.

The paper read was :-

SOME RECENT ADVANCES IN THE BIOLOGICAL THEORY OF SEX.

By JULIAN S. HUXLEY, M.A.,

Fellow of New College, Oxford.

It is with some misgivings that I have chosen as my subject one which is so intertwined with our whole existence, physical and mental, as that of sex. There is a mystery about the simple fact of sex which rivals the mystery of life itself. It may, I suppose, occur that certain individuals and certain races take sex as given, and bother their heads no further with it. But once the attention of the human mind has become entangled with the problem, unsatisfied wonder and curiosity are begotten, and in their turn beget a varied progeny of myth and tabu, of legend and doctrine.

It is impossible to touch on many of the points that arise. The latter-day psychologists have shewn us how primitive instincts, such as those of fear and of sex, wind themselves round the roots of all mental life, become sublimated by the acquisition of new objects, and are parts of the indispensable subterranean driving force of mind.

The evolutionists have given us a glimpse of the secondary changes which sex has wrought in the history of life. Given separate male and female organisms on the one hand, and a certain level of mental organisation on the other, there will follow, as a result, a need for stimulation of one sex by the other. This, in its turn, will lead to the development of striking and beautiful colours and structures, sounds and displays, either in one or in both sexes. Through this machinery of cause and effect, sex has led to the establishment in animals of all that beauty of form, colour, and voice, which is not the product of mere regularity and symmetry, of a sense of speed or power, or of the fitness of a structure for its purpose.

With this side of the problem, however, we cannot here deal. We are to concern ourselves with the subject of sex-determination, a subject which is not only of interest for its practical bearings, but because it is a focal point where cytology, genetics, pure zoology, embryology, and physiology meet, and because it promises to throw valuable light upon all these branches of biological science.

I may be pardoned if I begin by running over a few fundamental facts. All organisms, then, are composed of one or a multitude of cells (if we omit the bacteria, whose organization cannot properly be called cellular). Each of these cells consists essentially of a mass of living substance, containing a nucleus, also of living substance, but of a special nature. Whenever the cell divides—and growth in higher organisms is in the main a matter of cell-division—the nucleus resolves itself into a number of denser bodies, the so-called chromosomes, whose number and shape are constant for each different species. Each of these divides longitudinally when the cell divides, and one half of each passes into each daughter cell.

The essential sexual act is the union of the nuclei of two cells. Usually these cells—styled gametes or marrying cells—are of two kinds, male and female, the male cell or spermatozoon being generally small and active, the female cell or ovum being large, passive and full of reserve food substances. But in many of the lowest forms of life the gametes are almost or quite alike; thus at the outset we are met by the apparent paradox that a difference between two sexes is not implied by the existence of sexual fusion. The paradox comes from the historical fact that sex-difference was recognised before the nature of sexual fusion was understood or even discovered, and that, consequently, the word sex etymologically implies a difference.

The problem of the value of sex to life is on the way to a definitive solution. We find that the primitive form of reproduction in organisms is asexual—the creature divides into two, or buds its offspring. The sexual act, in the simplest forms, is a total fusion of two individuals, and, far from being subservient to reproduction, stands in its way. During the time that it takes, two or three asexual generations might have been produced.

What advantage, we immediately ask, is conferred by this sexual fusion that can compensate for the delay it causes in the process of reproduction?

Once more we must return to fundamentals. Genetical research since the re-discovery of Mendel's laws has made it increasingly certain that all, or almost all, of the hereditary constitution of an animal or plant consists of a series of actual chemical unities, the hereditary

factors or genes. Furthermore, we can be almost certain that these factors, whose existence we must predicate from our breeding experiments, are actually lodged in the chromosomes of the nucleus, where each one has its appointed station.

In a sexually-reproducing organism, these factors are always (with certain later-to-be-mentioned exceptions) present in duplicate; one member of each pair has come from the father, one from the mother. When the time for reproduction is approaching, the chromosomes arrange themselves in pairs, and at one particular cell-division the two members of the pair separate undivided from each other, so that each gamete has half the number of chromosomes characterising the species.

This is known as the reduction-division. There are details associated with it into which we cannot enter here; but for our purpose the nett result of the process is roughly that every gamete contains one or other, but never both, of every pair of hereditary factors in the organism's constitution.

It should be noted that whereas in the male all the cells produced become functional male gametes or sperms, in the female this is not the case. The female gamete, or ovum, must be large in order to start the developing embryo quickly and efficiently on its way. Its growth period occurs before the last two cell-divisions; and, so, in order that it may retain a respectable size, these last divisions are unequal, first one and then a second minute cell being separated from a much larger cell. The small cells are called the polar bodies, and speedily degenerate: the large cell remains to function as the ovum. One of the two divisions leading to the polar body formation is the reduction division.

The sets of factors are like packs of cards, and each organism is given two packs with which to play the game of life. But while the ordinary pack has fifty-two cards, the different hereditary factors are to be numbered certainly by hundreds, or more likely by thousands. Each card of an ordinary pack has a fixed value; a king is always a king, a ten always a ten. But here the cards may vary, or mutate, as we say; and the variation may be of such a nature that the card is of more value or of less value in the game which is life. It is, in fact, through the selection of these

variations, by the preservation of some and the dropping out of others, that life advances along the evolutionary road.

Now when sexual fusion occurs, the two packs of factors are separated from each other, each gamete receiving a single pack. One pack came originally from the father, one from the mother. But the redistribution to the gametes is at random; so long as one whole pack goes to each gamete it is no matter how many of its component factors come from the father, how many from the mother. Thus, with the great number of factors in each pack, it is extremely unlikely that any two gametes will be identical in the factors they receive.

Here is the key to our first riddle of sex. If there were no sexual fusion, the factors, in the longitudinal splitting of the chromosomes, would each be divided at every cell division, and parent and offspring would be identical save for rare aberrations of division. When a variation arose it would be propagated further; but it could not be recombined with another variation arising in another stock. Where there is sexual fusion, however, there is a ceaseless shuffling and re-dealing of the factors. The union of gametes from two separate stocks can recombine variations which have arisen independently in time and remotely in space. If the two variations are both favourable and reinforce each other, the possessors of both will be given great advantage in the struggle for existence.

In brief, the evolutionary responsiveness of a race, its plasticity, is enormously increased through sexual fusion.

Two of the chief theories held in the past as to the rôle of sex have been diametrically opposed to each other; one maintaining that sex made for rapid evolutionary change, the other that it ensured stability. Both are, as a matter of fact, in their way correct. Changes occurring in the constitution of some members of a species can, through sexual fusion, be commingled with the changed factors from other regions, and so the more or less accidental crystallizing-out of special sub-races, elementary species and local varieties may be prevented, or, at least, delayed. On the other hand, if the environment is changing, sexual fusion will permit of the combination of any new variations that may crop up, and so permit of a far more rapid change than does asexual reproduction. Put mathematically, if n inventable variations occur in a given

period, then with asexual reproduction n different types are possible; but with sexual fusion, 2^n different types.

Sex is the basis of evolutionary plasticity for all organisms of a complexity great enough to demand a complicated hereditary constitution comprised of many unit factors.

The bacteria possess no nucleus, no chromosomes, they appear to be so simple that they need no such regulatory mechanism of heredity. In consequence, they are sexless. In all other groups of organism, so far as known, sex is found. Some individual members of certain groups seem to have abandoned sex altogether; bananas, for instance, are propagated entirely by vegetative methods. Other species are hermaphrodite, and practise continual self-fertilization; these have abandoned, not sex itself, but all the evolutionary value of sex, since in them there is no crossing of stocks.

In the vast majority of organisms, however, crossing of stocks does occur; and

in many plants and in the majority of animals, the male and female gametes are produced by separate individuals—there are what we call two separate sexes. The problem is presented, in all such forms, of maintaining these two kinds of individuals; in approximately constant proportions, within the single species. The males of a species are often far more different from the females than they are from the males of related species or even of related genera or families. How can the single biological unit of the species exist under this double form?

Analogies are to be found. The common primrose, for instance, is found in two forms, the one pin-eyed with long style and short anthers, the other thrum-eyed, with the style and anthers in the reverse position; this dimorphic condition is of advantage, as Darwin long ago pointed out, in securing cross-fertilization. Breeding experiments carried out by Bateson showed that the constant presence of these two

FIG. 1.—Nine-banded Armadillo (*Tatusia novemcincta*.) Four foetuses attached to one placenta and derived from one ovum. (From a specimen presented to the Cambridge Museum by Dr. H. H. Newman.)

types within the species was ensured by the simple device of having one type usually hybrid or impure, or, in the jargon of mendelism, heterozygous.

Short-style (call it S) is dominant to long-style (call it s). Long-style plants are ss in constitution; most short styled plants are Ss, and will form S-bearing and s-bearing gametes in equal number, whereas all the gametes of the long-styled plant will bear s. Thus combinations s and s (or long-style) and s and S (or short-styled) will be produced in equal numbers in the next generation.

We must remind ourselves at the outset that various facts of general biology speak strongly for the view that sex in the higher animals is usually predetermined at the moment of fertilization. The best evidence on this point is afforded by the study of twins. Human twins may be no more alike than are ordinary brothers and sisters, and if so may be of opposite sexes; or, in the case of so called identical twins, they may be so alike that confusion is possible between them, and if so are always both of one sex. When this is so there is evidence, drawn from the embryonic membranes, that both members of the pair have been derived from a single fertilized ovum. In animals, members of the same litter are usually twins of the first type, without special resemblance; but in the Texas Armadillo, it has been found that the four young invariably produced at a birth always show the closest resemblance to each other, always are of the same sex, and always have a common embryonic membrane. The researches of Newman have finally shown that the four are actually budded out from an originally single embryo at a very early stage of development.

It thus appears certain that identical twins are produced by the division, normal or accidental, of a single fertilized ovum, while other twins are products of separate sets of sexual fusion. Both kinds of twins are subjected to identical condition in the mother's uterus, and yet only twins derived from one ovum are usually of the same sex.

What is it in the fertilized egg which thus appears to determine the sex of the embryo arising from it?

Some twenty years ago, an American zoologist noticed that the chromosomes of various insects differed in the two sexes; the male had one less than the female.

Later work has shown that there is, as a matter of fact, a similar sexual difference in the chromosomes of a large number of animals. The simplest form of difference is the total absence of one chromosome from the constitution of the male.

The chromosomes in which the sexual difference is found are usually designated sex or better X-chromosomes. The female then possesses a pair of X's, the male but one. In other species, while the female is of similar constitution, two unlike chromosomes, called X and Y, are present in the male.

It was speedily pointed out that these chromosomes would provide a mechanism for sex-determination. If, for instance, (as in some flies) the female is XX, the male XY, then all the female gametes will contain X; but half the male gametes will contain X, the other half Y. If the first class of male gametes fertilize an egg, the resultant individual must be XX—*ergo* female; if the second, the offspring must be XY—*ergo* male.

Similar reasoning will apply to those species in which the male X chromosome has no mate. These types of sex-chromosomes, as they are called, are found in most insects, and in mammals, while a variation occurs in certain worms. The precise reverse—where the male has a pair of similar chromosomes, the female a dissimilar pair or but a single one—is to be found, strangely enough, in one whole group of insects, the butterflies and moths, and in birds.

If the factors of heredity are in reality borne in the chromosomes, and the factor for sex is in some way located in the X chromosome, then it is clear that in all animals with sexual differences in their chromosomes, one sex is pure or homozygous for the sex-factor contains it in double dose; while the other is impure, heterozygous, and we have a real parallel with the case of the Primrose.

The supposition that the sex-factors are as a matter of fact lodged in the X chromosomes, has received strong support from breeding experiments.

It has for long been known that the inheritance of certain characters is what is known as sex-linked. Such a character, for instance, is the human disease known as hæmophilia, or excessive bleeding. Bleeders are almost invariably males; but they always inherit their dispositions to the disease through their mothers. Many precisely

similar cases, where females transmit while males are affected, have been found in the little vinegar-fly *Drosophila*, through which we have gained so much of our detailed knowledge of the processes of inheritance—that puny creature, which from its convenient habit of breeding comfortably in bottles, and providing a new and abundant generation every two or three weeks, is immortalized in the history of science.

The wild fly has red eyes; a mutation was found with white eyes—a male. This male, mated to a normal female, produced nothing but normal offspring. Of these, the males never fathered any white-eyed children, but the females, whether mated to their brothers or to other red-eyed males, produced children of whom all the females and half the males, were normal, but the

with another white-eyed male, half of *all* the offspring, both female and male, were white-eyed. Finally, if a white-eyed female were mated to a normal red-eyed male, the curious phenomenon of criss-cross inheritance was observed—all the daughters resembled their fathers, all the sons their mothers.

In *Drosophila*, the female has two X chromosomes, the male an X and a Y. If we suppose that the X chromosomes, besides being concerned in sex, bear the factors for other characters, and that the Y chromosomes do not carry any such factors, then these characters will be inherited exactly like "white-eye" or other sex-linked characters, as the accompanying diagram will show.

Sex-linked characters are found in other animals as well. But where, as in moths, it is the male that possesses two X chromosomes, the female but one, they are inherited in a way the very reverse of that which we have just seen. They are transmitted through males and appear in females; and a precisely similar mode of inheritance is found in birds.

Practical results have already flowed from these facts. As every poultry-breeder knows, it is impossible to tell the sex of an ordinary chicken at hatching. The secondary sexual characters of comb, wattles, spurs, voice, instincts and plumage do not develop until the reproductive organs begin to exert their effect. But when a cross is made into which a sex-linked factor enters, this does not need the secretion of the reproductive organs to express itself as a visible character, and is often obvious at birth. In a cross between a Barred Plymouth Rock hen and a Brown Leghorn cock, for instance, the sex of the chicks can be told at birth by the presence or absence of a white patch in the back of the neck. Crosses between silver and gold birds, made in the right direction, will also give chicks that can be sexed at hatching. If it is desired to do business in day-old chicks, they can thus be all guaranteed female, and the males kept for fattening and eating as young cockerels; and, as a matter of fact, some such procedure is being adopted by various large breeders.

So far there is a strong correspondence between the facts concerning chromosomes observed through the microscope by cytologists and the facts concerning sex-linked characters observed by experimental

FIG. 3.—Diagram of sex-linked inheritance. *Drosophila*: red-eyed female by white-eyed male. (After Morgan).

remainder of the males were white-eyed. The scheme of inheritance was identical with that of hemophilia in man—transmission through females, appearance in males. So far, white eyes had only been met with in males. But on crossing the daughter—herself red-eyed—of a white-eyed father

breeders in their stocks—a strong presumption that there exists a causal connection between the two sets of facts. Nature, however, has happily provided us with an *experimentum crucis* of her own designing—a tangled and complicated affair, whose unravelling we owe to the distinguished young American worker, Bridges, but which, once unravelled, has finally clinched the matter.

We have just seen that when a white-eyed female *Drosophila* is mated to a red-eyed male, criss-cross inheritance results, all the daughters being like their father in eye colour, all the sons like their mother. Certain females, however, were found to give abnormal results, producing white-eyed females and red-eyed males, as well as the ordinary two types.*.

Bridges came to the conclusion that this could be explained if the white-eyed females had arisen from an egg in which, through some abnormality, both X-chromosomes had remained in the egg, neither had passed into the polar-body; and the egg had then been fertilised by a Y-bearing sperm. If this were so, two chief results should follow. In the first place, the exceptional females should go on giving exceptions in their offspring; and in the second place, the tissues of the exceptional females, when examined under the microscope, should contain three instead of two sex-chromosomes—two X's and a Y. Both conclusions, together with other minor consequences prophesied by Bridges, were verified, and the proof that X chromosomes are concerned both in the determination of sex and in the carrying of sex-linked factors is now as perfect as that obtained in a good physical experiment.

One interesting further point is to be noted. In the first place, these XXY individuals were perfectly normal females: the presence of the Y, normally only found in males, did not influence them in any way (save by causing hereditary exceptions in their offspring). Further, there have been found males, produced by a similar abnormality of polar-body formation, with one X but no Y. These are normal in appearance, but fail to produce normal sperms, and are sterile. These facts make it clear that the Y-chromosome, in *Drosophila*, at least, is only necessary as a partner

to the X during gamete-formation, but is neither concerned in the determination of maleness, nor with the carrying of hereditary factors. One dose of X or of something in X normally produces a male, two doses a female. We shall see later that the dosage of this "something in X," this *sex-factor*, as we must call it, must be in a definite quantitative proportion to other factors.

In this instance, then, the exception did most definitely prove the rule. It may be mentioned that recent breeding work goes to show that in *Drosophila* there are certainly over 500 and probably over a thousand sex-linked factors in the X chromosome. It should further be noted that the sex-linked factors are only connected with sex by being lodged in the sex-chromosome. The characters which they concern need have nothing to do with sex, and the sex-linked factors are mostly concerned in the general development of the body in the same way as are most of the factors contained in all the other chromosomes. There are, of course, in most animals, characters in which the two sexes differ—the secondary sexual or sex-limited characters. The factors for these, however, are present in both sexes, as we may see when, for instance, a hen Reeves pheasant is crossed with a male of another species, and, although she herself shows none of the brilliant and distinctive colouring of the Reeves cock, yet transmits it to her male offspring. In other words, sex-linked characters are those whose factors happen to be carried in the sex-chromosome; and the sex-chromosome somehow acts like a switch, turning on not only maleness or femaleness, as the case may be, but also all the secondary characters associated with sex. But to this we shall have to return.

In *Drosophila* we have certainty as to the causal connection of the X-chromosomes with sex. And this certainty reverberates on to the probability found in other species, and increases it. It is now generally held—and apart from the intrinsic probability of the view, no adequate rival theory is in existence—that wherever sex-linked inheritance is found, there must exist one sex with two X chromosomes, the other with one.*

One interesting consequence of the dependence of sex upon sex-chromosomes, and

* As a matter of fact, Bridges obtained his results chiefly with another sex-linked character, "vermillion eye"; since the principle is identical, however, we continue, for the sake of simplicity, to use white eye colour as our example.

* When a Y chromosome is present it appears usually to carry no ordinary factors. A *Drosophila* without a Y cannot only exist, but is normal in appearance. It is, however, sterile.

one which may have some practical importance, deserves mention here. It will be remembered that in birds and moths it is the female which possesses but one X-chromosome, and forms, therefore, two sorts of eggs, one with an X and one without. It will also be remembered that in female animals, the reduction-division takes place during polar-body formation, so that in any given ovum the X chromosome can either stay in the egg and play a rôle in the embryo, or be thrown out into the polar body, and come to nothing.

Theoretically, then, if we could discover some means whereby, in moths or birds, we could influence the behaviour of the X-chromosome at the reduction division, causing it to remain in or to be cast out more often than usual, we should influence the sex-ratio. Now, this has actually been done in moths. Seiler finds that in a certain species, the proportion of males was markedly increased by exposure to high temperature during the reduction-division, or by causing retention of the eggs in the female's body for an abnormally long time before fertilization, but was markedly decreased by similar exposure to low temperature; and was further able to show that this actually depended upon the movement of the X-chromosome at reduction, high temperature causing it to remain more often in the egg, and vice versa. The proportion of females to 100 males, was only 62 at 35°-37° C., but 155 at 3°-5° C.

The work of Riddle goes to show that similar causes may be at work in pigeons. Here it would appear that the chemical activity of the bird in general is reflected in that of the egg, and that this, in its turn, affects the movement of the X-chromosome at reduction. Active metabolism leads to small eggs; in these, the X-chromosome is usually retained; and a preponderance of males is the result, and vice versa. It cannot be said that the final proof has yet been given for these birds, but after Seiler's work, there exists a very strong probability that we shall be able to find some agency which, in domestic birds, will affect the movement of the X-chromosome, and so alter the sex-ratio to suit our wishes.

It might seem, then, that the sex problem, so far as determination is concerned, was definitely settled. The X-chromosome mechanism is beautifully designed to give in each generation males and females in

equal proportions; it certainly operates in some animals; it must, said some biologists, be the rigid rule for all.

But many points remained unexplained. In the first place, the explanation was not complete. It left us with the chromosome sex-difference on the one hand, the adult sex-difference on the other, but no notion of how the former difference was translated into the latter during the processes of development. It was not a physiological explanation. In the second place, the ratio of the sexes is by no means always equal; in some animals, including man, there are born more males than females, in others the reverse is the case. Sometimes the sex-ratio at one season is different from that of another; possibly it may differ in some species according to the age of the mother. How are we to account for all these facts on the sex-chromosome theory? Finally, how are we to account for the various types of sexual abnormality, up till recent times all lumped together under the general term of hermaphroditism, which occur in man and many animals?

A study of these abnormalities will, as a matter of fact, be our best approach to a further analysis of the problem. It has long been known that in some animals, notably in insects, strange sex-monsters

(1).

(2).

FIG. 4.—(1) Pine moth, *Bupalus piniarius*, female on the left, male on the right, slide. (2) Gynandromorph Ant (*Myrmica scabrinodis*), characters of the male on the left, those of the worker on the right.

known as gynandromorphs from time to time occur, in which the creature is a mosaic of male and female characters. Very often they are bilateral—i.e., one half of the body is entirely male, the other half entirely female. Very remarkable appearances may thus be produced. In ants, for example, and some wasps, one side may be male and therefore winged, the other worker-female and therefore wingless.

When good fortune has brought up a gynandromorph among a brood of insects which are heterozygous for a sex-linked character, it is found that this too may be different on the two sides of the body.

For instance, a factor which produces short wings in *Drosophila* is lodged in the sex-chromosome. If a short-winged male be crossed with a normal female, inheritance will be according to the following diagram; (we use *s* as the symbol for the factor which produces short wings, *S* for the similar factor producing normal wings. *s* is recessive, so that an individual with constitution *Ss* appears normal).

When bilateral gynandromorphs appear in such a brood, they are sometimes normal-winged on both sides, sometimes normal-winged on the female side, short-winged on the male side. If the animal is also hybrid for non-sex-linked characters, these, however, are *never* different on the male and female sides.

From a multitude of similar facts, it can be concluded definitely that in *Drosophila* the cause of gynandromorphism is a lagging of one of the X-chromosomes after one of the early cell-divisions of a female embryo, and its consequent failure to become incorporated in the resulting nucleus. This nucleus will only possess one instead of two X chromosomes, and all its descendants will show male characters.

Bilateral gynandromorphs can only be produced if the abnormality occurs at the first division of the fertilized egg; if it occurs at the second division, one quarter of the body will be male; and so forth. Gynandromorphs in *Drosophila* are therefore all originally females in which certain definite areas of the body, through an abnormality of chromosome behaviour, have become male. They are spatial mosaics as regards sex.

In other insects, as for instance bees, gynandromorphs may occur. Here again it is quite clear that the female parts have two X chromosomes, the male parts one, and that an abnormality of division is at the bottom of the matter—although the precise type of abnormality is probably different.

Gynandromorphs thus constitute another and important piece of evidence for the sex-chromosome theory. They do not, however, throw further light on the chromosomes' mode of action. For this we must turn to another type of abnormality, the so-called hermaphrodites obtained by crossing certain races of moths. In this field, remarkable results have been obtained by the German biologist Richard Goldschmidt. His laborious researches, carried out over a series of years and developed as time went on with great analytic power, have given us a new concept—that of developmental intersexuality, as opposed to hermaphroditism or gynandromorphism. They are further a striking example of the value of genuine scientific method in eliciting the real meaning of well-known facts. It had long been known to entomologists that crosses between closely related species of moths, and more particularly between the European and Japanese species of that notorious forest pest the Gipsy Moth (*Lymantria dispar* and *L. japonica*) gave a considerable proportion of animals which were intermediate between male and female. This it was which first attracted Goldschmidt to the problem.

As a result of his breeding work, he found that the different races of *Lymantria* could be arranged in two series, which he calls *weak* and *strong*. If a "weak" male is crossed with a "strong" female, the offspring are normal. But if the cross is made in the opposite sense, then, while 50% of the offspring are normal males, the other 50% are more or less intermediate between males and females. These we call intersexes, and, as we shall see later, they are

FIG. 5 — *Lymantria*: female intersexes. Top, slight degree of maleness. Bottom, almost complete transformation to male (After Goldschmidt).

much more male than the offspring of other less strong races; and similarly the same "strong" race crossed with one "weak" race would give abnormal forms which were scarcely to be distinguished from ordinary females, while when crossed with another, it would give a strongly male type of intersex. The second weak race would thus be called "weaker" than the first.

On the basis of his results he was soon able to prophesy, and to prophesy correctly. If strong race A with weak race P had proved to give moderate intersexuality, while with race Q it gave strong intersexuality; and if further, another strong race B had given moderate intersexuality when crossed with Q, then it could be safely prophesied that this second strong race should give only a slight degree of intersexuality when crossed with race P, and so forth (see table).

It was further found that the racial character of "weakness" was always transmitted in the female line alone, possibly through the agency of the cytoplasm of the egg. But the character "strength" behaved like any other Mendelian character, or, rather, I should say like any other Mendelian sex-linked character. It behaved, that is to say, as if it were in the sex-chromosome, or as if it were the sex-chromosome. From analogy with other cases, there can be no reasonable doubt that this character for "strength" is actually what we usually call the sex-character itself—the something in the sex-chromosomes which is connected with the determination of sex.

But, as we shall see more in detail later, the determination of sex is an affair of

Races.		Degrees of Intersexuality.				
Strong.	Weak.	Very marked.	marked.	moderate.	slight.	Very slight.
A	P	$A \times R$	$A \times Q$	$A \times P$	$B \times P$	$C \times P$
B	Q		$B \times P$	$B \times Q$	$C \times Q$	
C	R			$C \times R$		

really females modified in the direction of maleness. Further, he found that the races within each group differed among themselves. Some "strong" races were very strong; the intermediate forms produced when these were used as parents were

balance between the sex-factor properly so-called, and other factors. The same is obviously true here. A change in the sex-factor itself will affect the degree of intersexuality after a cross, but so also will a change in the factor concerned in "weakness."

It is of considerable interest from a general evolutionary standpoint to find that "strength" and "weakness" are bound up with geographical distribution and with the requirements of the life-cycle. Most Japanese races, for instance, are "strong." The most northerly, however, are "weak;" they inhabit a region whose annual temperature-curve is similar to that of Central Europe, and have a rate of growth similar to that of the "weak" European races.

This in its turn is connected with the most curious fact about the abnormal individuals; they are not intermediate like a gynandromorph, one half male and the other half female. They are not sex-mosaics in space, *but in time*. They start their development as normal females; at a particular moment they come to a critical point, change their mode of life, and finish their career as males. Since the hard parts of an insect are external, and composed of the dead material chitin, any of them which are laid down before the change remain unaltered after it, so that by an inspection of the parts which are normally different in the two sexes, it is possible to say of any particular intersex just when during its life-history it came to the moment which switched it over from one sex to the other.

It is clear that if the change were to operate very early, before any of the hard parts were formed, then we should get an animal which, although it possessed the chromosome-constitution of the female, and had actually started to develop along the paths which lead to the condition which we call femaleness, yet was indistinguishable by any ordinary test, whether of appearance or behaviour, from a normal male. And as a matter of fact, in certain crosses the offspring, instead of consisting of 50% males and 50% intersexes, consist entirely of males. 50% of these are normal males, but obviously the remainder are transformed females, and instead of having the normal chromosome constitution of males, which in moths is XX, will possess that of females—XY. This being so, such transformed males, on being bred from, will not give the normal sex-ratio at all—but that is another story, to which we must return later.

The first and most startling thing to realise is that an individual predetermined, as it were, for one sex may be transformed into an individual of the other sex, and may beget offspring normally in its transformed condition.

Besides female intersexes, which ought to be, and start as, females, Goldschmidt has also found male intersexes. The conditions for their genesis (since the male moth is XX in constitution) are more complicated, and they usually only appear in the second generation after an inter-racial cross. As would be expected, the male intersexes do not resemble the female intersexes, except in the one particular of combining male and female characters in their single persons. But in them the male characters are to be seen in early-developed parts, the female characters in those which are formed later, after the predestined turning-point.

We inevitably ask ourselves what is this strange mechanism which permits the animal to develop normally up to a certain stage, and then forcibly swings it over into the alien paths proper to the development of the opposite sex. The answer is apparently to be found in some simple difference in rate of chemical reaction between the sex-factors of the "strong" and the "weak" races.

We are by now for the first time in a position to be able to go back to first principles in our subject, and to realise something of the *raison d'être* of the sex-chromosome mechanism.

In the first place, as we have seen, the arrangement by which one sex contains the sex-factor in single dose and is heterozygous for it, as the Mendelians say, while the other sex contains it in double dose and is homozygous for it, is the simplest way of ensuring a 1:1 ratio of the two types.

What really occurs when an egg with one chromosome-constitution turns into a male, one with another constitution into a female? There are plants, such as *Polygonum amphibium* and the water ranunculus, which will develop into ordinary-looking land plants when growing in a dry environment, but assume a typically aquatic appearance, with floating leaves and hollow stem, when growing in water. The determining factor is here the external environment. In all higher animals, however, it is the internal environment which is of chief importance, the animal's metabolism, the chemical processes of its life, the composition of its body fluids, and so forth. The difference in chromosome constitution between the two sexes seems to bring about a difference in the internal environment of the developing embryo,

one type of internal environment allowing male characters to develop, the other favouring the appearance of female characters. Now it appears that there are two definite substances which directly or indirectly are responsible for the development of one or other of the two types of internal environment. We may have one which we may call, in a short-hand way, the female-determining substance, because it is responsible for producing the female-determining environment, the soil which encourages the growth of female and suppresses that of male characters; and the other in similar fashion we may call the male-determining substance.

These two substances in their turn are produced, apparently directly, by the sex-factors in the hereditary constitution. In moths, it is the factor for maleness, for producing the male-determining substance, which is present in the X-chromosomes. It is, therefore, present in double quantity in the male, in single quantity in the female. The female-determining substance, on the other hand, is produced by the female sex-factor, which exists in the same dosage in all eggs. If we call the male-determining factor M and the female-determining F, then we have a quantitative relation between the two such that 2M is greater than F, while F is greater than 1M.

But this is not all. These sex-factors are in some way giving rise to the sex-determining substances. Perhaps, as Goldschmidt suggests, they are actually enzymes, ferments. Be that as it may, it is clear that the rate at which the sex-determining substances are produced must continue to bear a pretty constant relation to the quantities of the sex-factors present in the constitution, if the two types of internal environment are to be produced correctly. But now suppose that we found a race of moths whose sex-factors had the property of working faster than normal, of producing more sex-determining substance in a given time than do the sex-factors of other races. What will happen if a male of the faster-working race is crossed with a normal female? The female sex-factor is always inherited through the mother. All the offspring, therefore, will have female-determining substance produced in them at normal rate. The male will possess one normal and one quick-working male-determining sex-factor; they will thus produce more male-determining substance than usual in relation to the

amount of female-determining substance.

The females, on the other hand, will contain only one male-determining factor, and that will come from their fathers, and therefore be quicker-working than usual. As a consequence, the amount of male-determining substance produced will gradually increase relatively to the amount of female-determining substance, and finally catch up with and surpass it. When it does this, it automatically switches on, so to speak, the male-determining environment, making it impossible from now on for any but male characters to develop. The animal, in fact, is a female intersex, and the case we have been considering is that of a cross between a "strong" male and a "weak" female. So-called strength and weakness are only signs of greater or less rapidity in the production of male-determining and female-determining substances.

An identical result would have been obtained if the male had been less "strong" but the female parent much "weaker" than normal. It is not the absolute, but the relative rates of production of male and female-determining substances that count in the formation of intersexes. A diagram will make this clear. A *plus* sign signifies a "strong," a *minus* sign a "weak" sex-factor.

European female \times Jap male.

$M-F^- \times M+M+F^+$

To give male intersexes, it is necessary to combine a strong "female" factor with two weak "male" factors, and this will only occur in the second generation after a cross, as under.

Jap female \times European male.

$M+F^+ \times M-M-F^-$

Inexorably the sex-factors in normal development build in a series of stages, each stage conditioned by the one before, conditioning the one that comes after, and culminating in the blossoming of the characters associated with one sex or the other. As inexorably, when unequal sex-factors are mated together in an embryo, the one overtakes the other in the amount of substance which it can produce in a given time; and so two mechanisms, each of which by itself is designed to give normal-sexed individuals in normal proportions, give rise when combined to this relentless change of sex, rendering useless all the earlier part of the development, and producing (save in cases of complete sex-reversal) organisms which fall between two stools into biological uselessness.

It is worth noting the possibility which I frankly confess appears a doubtful one - that in animals of domestic importance to man we may be able to find races, geographical or otherwise, which when crossed would produce transformation of one sex. In mammals, if this were possible, the easier transformation would be the more desirable--from male into female.

This idea of the two internal environments, themselves determining one or other set of sexual characters, determined by the relative amounts and rates of working of the sex-factors in the constitution, will throw considerable light on to the conditions to be found in vertebrates.

In this highest group, affairs are more complicated; there appears to be another link in the chain. The internal environment determines the formation of a male or female reproductive organ, and this in its turn determines the appearance of all the other sexual characters by means of some internal secretion or *hormone* which it produces.

In insects, this does not occur. Castration, whether in male or female, whether in early or late stages, and whether followed or not by the transplantation of the reproductive organs of the opposite sex, is without effect upon the sexual characters of the body as a whole. It has been known for a very long time that this is not so in vertebrates, for castration has been practised on man and animals since time immemorial, and its effects must always have attracted notice. But it is only in the last few years that our knowledge has been put upon a broad and accurate basis.

The merit of the work of Steinach, Sand, Moore, and Lipschütz has been that, starting from a theoretical premiss, they have confirmed it by careful experiment. The premiss was the idea, first clearly enunciated by Ancel and Bouin, that the interstitial substance of the vertebrate reproductive organ produces a secretion or hormone which controls the development of all the other sexual characteristics of the body. Steinach took very young guinea-pigs, removed their reproductive organs, and then into some of them grafted reproductive organs taken from animals of the opposite sex. Those which were only castrated remained in many respects unchanged, in others assumed a neutral, intermediate aspect. Those, however, which in addition received into their circulation the secretion of the grafted reproductive organ of opposite sex became in most respects as if they were in reality of this opposite sex. Females became male in appearance and in instincts, males became female. Castrated males with grafted ovaries not only were attractive to normal males, but secreted milk and suckled young, exhibiting normal maternal behaviour, although, of course, they were incapable of actually producing offspring.

FIG. 6—Feminized male guinea-pig (testes removed, ovaries grafted in) suckling young. (After Steinach).

These experiments made it clear that the reproductive organs do actually secrete hormones which are specifically different in the two sexes; that the different sexual instincts of male and female depend upon the activating of different tracts in the brain, whose total potentialities are the same in both sexes; and that very considerable changes in bodily structure and rate of growth are due to the action of these substances even after birth.

The earliest stages of sexual differentiation, however, are pre-natal; and the work

we have been chronicling throws no light upon them. Fortunately, Nature herself is in the habit of performing an experiment of this nature, and the acuteness of Lillie enabled us to interpret it. It has been long known to stock-breeders that when twins are born in cattle, one of the pair is often abnormal in its sexual characters. These sexually abnormal individuals are known as free-martins. Various lines of evidence conspire to show that the free-martin is an abnormal female, and that it only occurs as one of a pair of twins, and only when the other member of the pair is a male. Lillie was able to demonstrate that when twins are produced in ruminants, the membranes of the two embryos coalesce into one. But whereas in sheep and goats, with rare exceptions, the coalescence is confined to the membranes, in cattle it always goes further and extends to the blood-system. From this it results that, in cattle, whatever substances are present in the blood of one embryo will be present in that of the other also. It appears that the reproductive organ of the male embryo starts to produce its characteristic hormone before that of the female; or possibly that it produces a more potent hormone. In any event, it is the presence of the male hormone circulating through the female embryo that influences its development, produces the strange intermediate condition seen in the free-martin, in which the internal organs are predominantly male, the external parts predominantly female, while the secondary sex-characters are intermediate.

If there were any doubt as to the correctness of Lillie's views, this has been dissipated by the remarkable experimental results obtained by Minoura in Lillie's laboratory. Minoura has been able to produce artificial free-martins, of both sexes, in chicks.

Removing a part of the shell of eggs in the second week of incubation, he grafted on to the vascular area of the embryonic membrane a small portion of reproductive organ, male or female, taken from another bird. When the reproductive organ was of the same sex as the embryo on to which it was grafted, no abnormality was to be seen, but when it was of opposite sex, far-reaching alterations were produced in the short period—6 to 12 days—that elapsed before the chicks were examined. Before hatching, of course, none of the secondary sexual characters—comb, spurs,

plumage, instincts—are developed. *Per contra*, it is the reproductive organs themselves, together with their ducts and accessory glands, which are being differentiated from the original indifferent state.

All intermediate stages, both from maleness towards femaleness and *vice versa*, were found in the operated chicks. After this result, it can definitely be stated that vertebrate embryos, whether male or female by chromosome constitution, pass through a more or less indifferent or neutral condition of their reproductive system, and that the conversion of this into the condition characterising one or the other sex is only possible as the result of the presence of the sex-hormone appropriate to that sex. Excess of sex-hormone of the opposite sex will divert the developing animal from its proper sex to an intermediate or reversed condition.

Two interesting points arise out of these results. Firstly, what is the reason that a male mammalian embryo is not influenced in its development by the female hormones derived from its mother's reproductive organs, and circulating in her blood? We can only say that there must be some unknown agency which prevents this, or else all male mammals would be sex-intermediates; and that another problem is here presented for solution to those who are interested in the interaction of mother and foetus.

The second, and more general point, is this: We see that the first sign of differentiation in the developing vertebrate reproductive organ is the production of a substance which, one may properly say, encourages itself. The female reproductive organs which Minoura used as grafts, were taken from fowls of all ages, from 10-day chicks to mature hens; the effect of all was the same—to help convert the indifferent type into the female type of reproductive organ. The same, *mutatis mutandis*, was true of the male organs used. I want to draw attention to the possibility that these specific substances produced by the reproductive organs are identical with specific substances present in the factorial complex that makes up the hereditary constitution. From Guyer's recent work we know that if the lens of a rabbit's eye is ground up and injected into fowls, and the fowl's blood with the resultant antibody is injected into pregnant rabbits, the young may show defects of their lenses, and that these defects may be inherited

through both sexes. This indicates that the substance of which the lens is composed is, in some particular, identical with the substance which determines its formation in development, and is transmitted in heredity. The specificity of the male and female sex-hormones in birds from the earliest to the latest stages of sex-differentiation, indicates a similar possibility for them. If so, unlimited fields are opened up for the joint efforts of genetics and immunology. I mention the possibility, since it is of the greatest importance that it should be tested, and since both geneticists and those interested in serum-therapy and immunity should bear it in mind.

It remains to mention one further experiment in this field. Some workers have interpreted these results to mean that there is a definite antagonism between the sex-hormones. Moore, however, has succeeded in grafting an ovary into a young rat from which one testis had been removed, and found that both male and female gametes grew to maturity in a normal way. It is, therefore, possible to balance the male and female hormones in one and the same individual, and so to produce an artificial hermaphrodite. The apparent antagonism seen in the natural and artificial free-martins, must be due to the fact that the reproductive system before birth or hatching is indifferent as regards its structure, and is in what the botanist call its sensitive stage, during which it may react to abnormal environment by alterations of structure, but after which it is no longer capable of so reacting. We saw a similar phenomenon in the case of the hard parts of the intersexual gypsy moths (*Lymantria*).

(To be continued.)

OBITUARY.

EDWARD HOPKINSON, M.A., D.Sc., M.P.—Mr. Edward Hopkinson died at his residence, Ferns, Alderley Edge, on the 15th inst. Born in 1859, he was educated at Owens College, Manchester, and Emmanuel College, Cambridge, where he obtained a foundation scholarship. He graduated as tenth Wrangler in 1881, and two years later was elected a Fellow of his college. In 1882 he became assistant to Sir William Siemens. He carried out experiments at Portrush on the first electrical tramway in the United Kingdom, and in 1883, in conjunction with Mr. Alexander Siemens, he read a paper on the subject before the Royal Society

of Arts, for which he was awarded a silver medal. In the same year he also received from the Institution of Civil Engineers a gold medal and the Telford Premium for a paper on the construction and working of the Bossbrook and Newry Tramway, which is worked by water-power.

He joined the firm of Messrs. Mather and Platt, of Salford, in 1884; he became a partner in 1887, and in 1899, and when the firm was enlarged by the merging into it of Messrs. Dowson, Taylor & Co., he was appointed vice-chairman. He was also vice-chairman of the Chloride Electric Storage Battery Company.

Mr. Hopkinson was associated with some of the largest developments in electrical traction. He received from the Institution of Civil Engineers the Telford and George Stephenson Premiums and Medals for his paper on the City and South London Railway; his firm were responsible for the original electrical equipment of the Douglas and Laxey Electric Tramway and the Snaefell Mountain Railway, and for the electric tramway between Blackpool and Fleetwood.

He was a past president of the Institution of Mechanical Engineers, a member of the Council of the Institution of Electrical Engineers, and vice-president of the Manchester Steam Users' Association. He also did much good work in connexion with the Salford Royal Hospital, and he was chairman of the Associates of Owens College, and a member of the Court of Governors. He served on the Indian Industrial Commission (1916-18), and on the Industrial Fatigue Research Board of the Department of Scientific and Industrial Research. He entered the House of Commons in 1918 as Unionist Member for the Clayton Division of Manchester.

FRUIT CULTIVATION IN CZECHO-SLOVAKIA.

Czecho-Slovakia has a climate particularly favourable for fruit growing except in the high mountainous regions, and apple cultivation was a flourishing business as early as the eleventh century. In spite of the successive wars which swept over Bohemia and Moravia, fruit raisers went on selecting and improving their stocks, protected by royal patrons and later by State laws.

According to a report by the United States Assistant Trade Commissioner at Prague, Czech nurserymen have succeeded in producing several varieties of fruit which have a good reputation in the near-by countries, particularly Germany. Among these are the "Borsdorf apple," the "virgin apple," the "raspberry apple" of Holovousy, the Solany pear, and the Colomas. The so-called "red apple of Stettin" (known in Bohemia as the "vejlimek") is of Czech origin, the seeds having been carried to Stettin by Czech emigrants who were driven out

of their country after the battle of the White Mountain.

Most of the orchards are in Bohemia and Moravia, and fruit culture was made more profitable there by the existence of so many species, giving good opportunities for grafting and production of new varieties. Many nurseries were occupied with this sort of work, the principal ones being those of J. Vesely at Molitorov, Mazanek at Soudna, Masek at Turnov (all in Bohemia), and Felbinger at Zilosee in Moravia. During the war these and other nurseries suffered somewhat, principally through not being able to get the wild stocks and grafts formerly imported from Germany, Holland, and France.

More than half the fruit orchards of Czecho-Slovakia are in Bohemia, or about 30,000,000 fruit trees. The districts which are richest in fruits are the regions in the vicinity of the Elbe, especially near Melnik, Litomerice (Leitmevitz), Jicin (Gitschin), and Kadan. Moravia has about 10,000,000 trees. Having, on the whole, a southern exposure and a warmer climate, the Moravian groves consist partly of trees which need a milder growing season, such as apricot trees. The richest sections of Moravia are the slopes of the Carpathians, where plums and apples are grown in connection with some of the stock farms, a profitable combination for the farmers. In Silesia there are 2,000,000 trees, but the exposure of this part of the State is northern and the winters are harsh and the springs late. In Slovakia there are about 10,000,000 fruit trees and in Carpathian Russia about 3,000,000. These districts, covering an area of about 23,910 square miles, have a climate which is favourable for fruit growing except in the alpine districts. However, the culture of fruit is much more primitive than in the western parts of the State.

In Slovakia there are still traces of the so-called "community orchards" which were established under the old Hungarian law. The idea of the "community orchard" was a good one, but in practice these orchards steadily deteriorated because they were placed in charge of Government officials appointed from Budapest, who secured their positions through influence and were apt to know nothing whatever about fruit growing.

There are said to be about 55,000,000 fruit trees in Czecho-Slovakia, of which four-fifths are bearing. Two-thirds of these are stone-fruit trees, and among them the "quetsch" plums are estimated to constitute about half of all the fruit in the country. These plums are found in great quantities in Bohemia, the ordinary plums growing in Slovakia (especially in Trencin) and Carpathian Russia, and both kinds in Moravia.

Pear and apple orchards are plentiful throughout Bohemia and Moravia—chiefly in the sheltered regions near Litomerice (Leitmeritz)—and in the Slovakian counties of Trencin (Trentschen), Tekov (Bars), and Hont.

Cherry orchards are found in all parts of the country, predominating in Moravia near Ivanovice (Eibenschitz), Znaim (Znojmo), Kyjov (Gaya, Gaja), and Hodonin (Goeding), and in Slovakia at Bratislava (Pressburg), Hont, Nitra, Krupina, Sabina, and Nove Mesto and Vahom (on-the-Vaag).

Apricots are found in Moravia near Zidlochovice, Hodonin and Straznice; and in Slovakia near Bratislava and Ostrihom (Estergom). Currants are grown in Moravia in the vicinity of Brno (Brunn), at Bosonoby and Jundrov, where there are also ancient vineyards, and at Devin near Bratislava. Peaches are not grown in considerable quantities anywhere.

It has been officially estimated that the total fruit harvest in Czecho-Slovakia in 1918 was almost 1,100,000 metric tons, of which 650,000 tons were grown in Bohemia and 93,000 tons in Moravia. Figures are not obtainable for Slovakia. Of this amount not all can be consumed by the home market, of course, and a large part is exported, while another large share is made into preserves. Before the war apples were the principal export, then "quetsch" plums, then pears (especially summer pears), then cherries. Exportation of fruit was chiefly to Germany, Russia, and Vienna. There is active trading in fruits in the regions of Litomerice and Lovosice (Lobositz), where ten per cent of the fruit orchards of Bohemia are found; in the districts around Louny (Laun) and Zatec (Saaz); and in those of Melnik and Prague which contain 9 per cent of the trees cultivated in Bohemia.

The preserving and canning of fruit was one of the few trades which the war enormously helped, as fruit was sent in large quantities to soldiers in the field and became one of the war staples. There are now about 400 factories producing all kinds of canned fruits in Czecho-Slovakia, particularly jams. In 1919 as many as 1,500 carloads of jams were made, for which 7,500 metric tons of sugar were used.

Fruit canning and preserving is also an important affair in every peasant household. The "quetsch" plums are especially prized, being either made into marmalade or dried on the drying stoves which one sees in many villages. The distilled juice of the "quetsch" and other plums is a highly prized drink in Moravia, and especially in Slovakia and Carpathian Russia. In times past the making of brandy was the only use made of plums in Slovakia and Carpathian Russia. According to Hungarian statistics, there existed in 1904—5 some 69,000 brandy distilleries in Hungary, of which 62,000 belonged to peasants and the rest to large industries. In that year home stills produced 200,000 hectolitres (4,400,000 Imperial gallons) of brandy, and the industrial stills 520,000 hectolitres (11,440,000 gallons) of brandy with a fifty per cent. alcoholic content. Of this total, about one-sixth, or 120,000 hectolitres (2,640,000 gallons), were made in Slovakia and Carpathian Russia. The greater part of this brandy was

consumed at home. In order to discourage the tendency of peasants to consume too much, the new laws forbid the making of plum brandy except by communities and agricultural co-operative societies.

MENTHOL PRODUCTION IN JAPAN

Menthol crystal is a Japanese product the use of which is constantly increasing. It is a residue from the refining of the oil distilled from a variety of peppermint grown in Okayama and Hiroshima Prefectures, in Yamagata, and in the northern island of Hokkaido. According to a report by the United States Commercial Attaché at Tokio, the greater part of the product comes from Hokkaido, where the mint crop is a favourite one for farmers owing to the distilling work it furnishes during the long and otherwise unprofitable winters. Plants of this region, however, are less rich in peppermint oil than those grown in Okayama and vicinity. The crystal finds its chief market in America, whereas the peppermint oil is sold mostly to England; before the war it went to Germany.

According to official figures issued by the Department of Agriculture and Commerce, the production of Menthol Crystal and peppermint oil in Japan during 1918 and the previous four years was as follows:—

Year.	Menthol crystal		Peppermint oil.	
	Pounds	Value	Pounds	Value.
		£		£
1918	440,290	284,000	520,533	75,000
1917	566,328	279,000	569,475	73,000
1916	471,550	233,000	541,081	72,000
1915	501,581	197,000	575,815	80,000
1914	320,164	160,000	326,665	61,000

Official figures have not been published for later years, but it is understood in the trade that the 1919 production was about 330,000 pounds for crystal, and the 1920 production 265,000 pounds of crystals and an equal amount of oil.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, JANUARY 30. Farmers' Club, at the Surveyors' Institution, 12, Great George Street, S.W., 4 p.m. Mr J. Mackintosh, "Milk Recording Societies and their Effect upon the Dairying Industry."

Mechanical Engineers, Institution of (Yorkshire Branch), Y.M.C.A., Abdon Place, Leeds, 7.30 p.m. Chairman's address.

Architectural Association, 34, Bedford Square, W.C., 7.30 p.m. Mr H. B. Creswell, "Ourselves."

TUESDAY, JANUARY 31. Illuminating Engineering Society and Royal Aeronautical Society (Joint Meeting) at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Lt.-Col. L. F. Blandy, "The Use of Light as an Aid to Aerial Navigation."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. H. H. French, "Our Old Village Churches and their Story."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. H. H. Turner, "Variable Stars." (Lecture I.)

Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Col. T. C. Hodson, "The Primitive Culture of India." (Lecture II.)

WEDNESDAY, FEBRUARY 1. University of London, University College, Gower Street, W.C., 5 p.m. Mr. H. G. Spearling, "The Development of Art in Crete and in Greece." (Lecture I.) 5 p.m. Sir Frederick Bridge, "Sir W. Leighton's Great Collection of Early 17th Century Motocro by Eminent British Composers." (Lecture III.)

United Service Institution, Whitehall, S.W., 3 p.m. Rev. H. W. Blackburne, "Existing Organisation and Work of the Royal Army Chaplains' Department."

Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Dr. R. S. Griffith, "The Virulence of Tuberculosis Bacilli and the Circumstances under which it may vary."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. H. T. Smith, "The Curse of Work."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. Annual General Meeting. (1) Messrs. J. L. Lizius, and N. Evers, "Studies in the Titration of Acids and Bases." (2) Dr J. C. Drummond, and Mr. A. F. Watson, "The Sulphuric Acid Reaction for Liver Oils and its Significance." (3) Messrs W. Dickson, and W. C. Easterbrook, "The Quantitative Separation of Nitrobody Mixtures from Nitro-glycerine."

Geological Society, Burlington House, W., 5.30 p.m.

Electrical Engineers, Institution of (Wireless Section), Savoy Place, Victoria Embankment, W.C., 6 p.m. Major J. Erskin-Murray (a) "The Determination of the Decrement of a Distant Sending Station" and (b) "Some New Methods of Radio-Navigation."

(South Midland Centre). The University, Birmingham, 7 p.m. Dr. S. P. Smith, "Single and Three-Phase Commutation Motors with Shunt and Series Characteristics."

THURSDAY, FEBRUARY 2. Royal Institution, Albemarle Street, W., 3 p.m. Sir Napier Shaw, "Droughts and Floods." (Lecture I.)

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. Messrs L. J. Romero and J. B. Palmer, "The Interconnections of A.C. Power Stations."

FRIDAY, FEBRUARY 3. Midwives Institute, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7 p.m.

Royal Institution, Albemarle Street, W., 9 p.m. Sir Francis Younghusband, "The Mount Everest Expedition."

Philological Society, University College, Gower Street, W.C., 8 p.m. Prof. Sir Israel Gollancz, Presidential Address.

Engineers, Junior Institution of, Caxton Hall, Westminster, S.W., 8 p.m. Major W. Gregson, "Utilization of Waste Heat from Internal Combustion Engines."

Chemical Industry, Society of (Manchester Section), at the Textile Institute, 10, S. Mary's Parsonage, Manchester, 7 p.m. Mrs. T. Callan and J. A. R. Henderson, (1) "The Estimation of the Nitro Group in Aromatic Organic Compounds." Part 2., and (2) "The Use of Potassium Bromate in Volumetric Organic Analysis."

SATURDAY, FEBRUARY 4. Chromatics, International College of, Caxton Hall, Westminster, S.W., 3.15 p.m. Rev. J. J. Pool, "Peacocks: The Splendour of their Plumage and the Effulgence of their Colouring."

Municipal and County Engineers, North Eastern Meeting and Wakefield.

Royal Institution, Albemarle Street, W., 3 p.m. Prof. E. de Sellincourt, "Humorists of the Seventeenth Century." (Lecture I.)

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday of the week preceding the Meeting.

*For Meetings of the ROYAL SOCIETY OF ARTS, see page 187

Journal of the Royal Society of Arts.

No. 3611

VOL. LXX.

FRIDAY, FEBRUARY 3, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 6th, at 8 p.m.
(Cantor Lecture). C. AINSWORTH MITCHELL,
M.A., F.I.C., "Inks." (Lecture III.)

TUESDAY, FEBRUARY 7th, at 4.30 p.m.
(Dominions and Colonies Section.) WILLIAM
TURNBULL, Timber Commissioner for the
Government of British Columbia, "The
Timbers of British Columbia." LORD
CLINTON, Forestry Commissioner, in the
chair.

WEDNESDAY, FEBRUARY 8th, at 8 p.m.
(Ordinary Meeting.) EDWARD VICTOR
EVANS, O.B.E., F.I.C., Chief Chemist,
South Metropolitan Gas Company, "Some
Solved and Unsolved Problems in Gas
Works Chemistry." SIR ARTHUR DUCK-
HAM, K.C.B., M.Inst.C.E., in the chair.

CANTOR LECTURE.

On Monday evening, January 30th, Mr.
C. Ainsworth Mitchell, M.A., F.I.C., de-
livered the second lecture of his course
on "Inks."

The lectures will be published in the
Journal during the summer recess.

NINTH ORDINARY MEETING.

WEDNESDAY, JANUARY 25th, 1922 :
MR. ALAN A. CAMPBELL SWINTON, F.R.S.,
Chairman of the Council, in the chair.

The following candidates were proposed
for election as Fellows of the Society : -
Beadle, Ormond Alec., Oxford.

Chettiar, Rao Sahib P.K.A.C.T. Veerappa.

M.B.E., Kottaiyur, Madras, India.

Oppenheimer, Maurice, Rangoon, Burma.

Taylor, Samuel Daniel, Oxford.

The following candidates were balloted
for and duly elected Fellows of the Society :
Chari, N. S. T., M.A., Calcutta, India.

Gibson, Mrs Marion Campbell, Perth, West
Australia

Gwyn-Williams, Captain R. H., O.B.E., M.C.,
Balaghat, Central Provinces, India.

Hardecastle, Charles Henry, Bombay, India.

Harding, Henry George Alan, F.C.S., North
Sydney, N.S.W., Australia

Lahiri, Purna Chandra, L.M.S., Dibrugarh,
Assam, India

Saksena, Ram Babu, M.A., LL.B., Saharanpore,
United Provinces, India

Stubbs, Roy Wilson, Karachi, India

Sturrock, George S., Lahore, Punjab, India

Watson, Edwin Alexander, Calcutta, India

A paper on "Photosculpture," was read
by Mr. Howard Maurice Edmunds.

The paper and discussion will be published
in a subsequent number of the *Journal*.

INDIAN SECTION.

FRIDAY, JANUARY 27th; SIR WILLIAM
S. MEYER, G.C.I.E., K.C.S.I., High Com-
missioner for India, in the chair.

A paper on "The Timbers of India and
Burma," by Mr. Alexander L. Howard,
was read by Mr. A. Arnold Hannay.

The paper and discussion will be published
in a subsequent number of the *Journal*.

CASES FOR JOURNALS.

Cases for keeping the current numbers
of the *Journal* are now obtainable. They
are in red buckram, and will hold the
issues for a complete year. They may be
obtained post free, for 7s. 6d. each, on
application to the Secretary.

BINDING COVERS FOR JOURNALS.

For the convenience of Fellows wishing
to bind their annual volumes of the *Journal*,
cloth covers can be supplied, post free, for
2s. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

EIGHTH ORDINARY MEETING

WEDNESDAY, JANUARY 18th, 1922.

PETER CHALMERS MITCHELL, C.B.E., M.A.,
D.Sc., LL.D., F.R.S., Secretary of the
Zoological Society of London, in the chair.

SOME RECENT ADVANCES IN THE BIOLOGICAL THEORY OF SEX.

By JULIAN S. HUXLEY, M.A.,
Fellow of New College, Oxford.

(Continued from page 202).

We have now dealt with the leading principles that have emerged from the recent study of sex in animals. It remains to consider some special cases in the light of these principles.

The Gipsy moth does not stand alone in showing the progressive change of an animal from one sex to the other. Mrs. Sexton and myself, for instance, have examined a number of sexually abnormal specimens of the little amphipod crustacean *Gammarus*, and found a similar state of affairs. This animal has the additional advantage of moulting throughout life; and we have been able to show that these intersexes retain the same degree of femaleness throughout, but become progressively more and more male with successive moults. This can only mean that a certain degree of femaleness was reached, that the animal was then switched over to maleness, and that the male-determining substance afterwards progressively increased. It is further interesting in showing that the accumulation of male-determining substance may be very slow, and that the change from full female to full male may, therefore, take a very considerable time. A *Gammarus* intersex with partially developed male characters is therefore intersexual in rather a different way from any intersexual specimen of the Gipsy moth. Not only is it changing from the mode of working of one sex to that of the other, but it possesses a mode of working which is actually intermediate.

Then Crew has recently shown that almost all the so-called hermaphrodite adult frogs that are occasionally met with, are in reality individuals at some stage from the transformation from a normal female to a normal male.

This, however, seems only to be a rare and extreme case of a commoner phenomenon. Hertwig and his pupils have shown that some pure races and many crosses of different races of frogs give results very similar to that found in the Gipsy moth, reproductive organs often starting as female and after a shorter or longer time being made over into male. The changes that occur in the adult frog are only more striking and more general.

The chief points that concern us here are as follows:—First, since there are no hard parts whose form is fixed once and for all, the intersexuality can only be detected during the comparatively short transition period. Secondly, the developing organism is much more susceptible to external agencies than the moth. Optimum temperatures during development, for instance, favour the development of females, while extremes, both of heat and cold, favour the development of males.

Thirdly, it has been found possible to alter the sex-producing mechanism by delaying fertilization. If a pair of frogs are separated after a portion of the eggs have been laid, and the remainder of the eggs fertilized after the lapse of about four days, all the offspring are males. Considerable openings are given here for a study of the agencies which affect the production of the sex-determining substances in the developing animal. It has been supposed that in mammals a similar phenomenon occurred, and that if a female was served early in the period of heat a preponderance of females would result; if late, a preponderance of males. The latest statistics published by Pearl, however (*Ann. Rept. Maine Agric. Exp. Sta.*, 1917), indicate that in cattle this is not the case. In other mammals the period of heat is longer, and in them the matter should be put to a careful test by practical breeders.

Finally, it is of interest to know that the frog is the only vertebrate animal in which offspring have been raised from an individual which has been transformed from one sex to the other. Crew (*Journ. Genet.*, 1921) found that one of the parent frogs he had used in certain breeding experiments was recognisably in the last stages of transformation from female to male. While all the other pairs gave offspring with a normal sex-ratio close to equality, this pair gave nothing but females (in a total of over seven hundred). This

is what would be expected if the normal male frog had one X chromosome, the female two, since all the gametes both of the normal female and the female transformed into a male which fertilised it would contain an X, and all the offspring would therefore be XX —i.e., female.

Similar abnormal sex-ratios due to transformation of females into functional males have been obtained by Goldschmidt in his moths.

The marine worm *Bonellia* is interesting to us from more points of view than one. It is remarkable for its extreme sexual dimorphism, the female having a bulky body a couple of inches long, with an enormously distensible proboscis, while the male is a fraction of an inch in length, and spends his life as a parasite upon the female. Baltzer has found that in this animal sex is usually determined by an accident of position. The eggs of the animal hatch out into free-swimming larvæ. If one of these settles down upon the sea-bottom, it becomes transformed, after passing through an indifferent phase, into a female. But if it chances to settle upon the proboscis of a mature female (it is quite possible that the larvæ are in some way attracted by the proboscis), it turns into a male. It appears quite certain that any larva can become either a male or female, according to whether it does or does not settle upon a mature female. Baltzer took larvæ at various periods after they had settled upon a female's proboscis, but before they had become completely male, and forced them to lead an independent life. As a result, he obtained intersexual forms, the degree of intersexuality varying with the length of time the larvæ had been allowed to remain upon the proboscis.

It is important to notice that a small percentage of larvæ which do not settle on a female's proboscis may become males instead of females, and that the slower-developing individuals among the females often pass through a short male phase, characterised by the production of sperm. Goldschmidt advances an ingenious hypothesis to cover these facts. He supposes that in all individuals, there is at first an excess of male-determining substance, but that the production of female-determining substance after a time catches it up. Further, he supposes that the secretion of the female's proboscis has an effect comparable to that of the thyroid hormone upon tadpoles,

FIG. 7.—*Bonellia viridis*, female, about half natural size. The four small crescent-shaped bodies to the right of the proboscis represent males drawn to the same scale.

of accelerating the process of development and differentiation as against the, in many ways, antagonistic processes of growth. When differentiation is rapid, the sexual organs and the whole organisation mature under the influence of the male hormone; when it is not accelerated, under that of the female. There is nothing inherently

improbable in this view; and in any case the conception of processes succeeding each other in time, of a male phase succeeded by a female phase, appears to be necessary.

In any case, it is clear that there need be no sex-chromosome mechanism in *Bonellia*; the switch machinery is here provided by the outer environment of the developing creature.

The same possibility of dispensing with a sex-chromosome mechanism is seen in the slipper-limpet, *Crepidula*, which has become such a plague to the oyster-fisheries in certain districts. This animal forms chains, the free-swimming young settling upon older individuals and growing up where they settle. It has been established that the animal, after making itself fast, passes first through a neutral phase, develops then into a male, then becomes hermaphrodite, and finally ends its days as a female—a sufficiently adventurous history, if the animal were but capable of appreciating the fact!

In one species, *C. plana*, Gould has found that the male phase only occurs if an animal is attached to or near a larger (i.e., usually a female) individual. If it is prevented from attaining this proximity, it passes directly from the neutral to the female stage.

We are immediately reminded of *Bonellia*, and the dependence of its fate upon contact or non-contact with the proboscis of a mature female. A further parallel is afforded by the fact that the male phase in *Crepidula* is characterised by a very considerable retardation in growth-rate, which is temptingly similar to the acceleration of differentiation in male *Bonellia*.

It is interesting to note that there are other species of *Crepidula* in which chain-formation does not occur; the animals always start as free-swimming males, and always are transformed after a time into sedentary females. In *C. plana*, apparently, growth is too intense at first to permit of differentiation during the period of the male hormone's activity, unless slowed down by the secretion which emanates from the mature females.

It is important to notice how the same elements recur, even though the details are so different, in moths, in *Bonellia*, in frogs, and in *Crepidula*. There is first something given in the constitution, which in its turn brings about the formation of male and female-determining hormones.

There is next the variable rate of production of these hormones, and, finally, the variable rates of growth on the one hand, of differentiation on the other.

I may be perhaps pardoned if I digress for a moment to point out the similarity of the factors of another interesting biological problem—that of metamorphosis. It has, of course, been known since Gubernatsch's work, that feeding tadpoles upon thyroid caused them to metamorphose precociously into frogs. Later research shows that here, too, there exist complex quantitative relations between rate of growth, rate of differentiation, and amount of thyroid substance present. Put in a rather unusual way, the facts are these. The animal passes normally through two successive phases—the tadpole phase and the adult. A certain type of metabolism characterizes the tadpole phase. One might possibly say that there are definite substances, the tadpole-producing hormones, circulating in the animal's blood. The thyroid is the organ which transmutes one phase into the other. Below a certain relative concentration of thyroid hormone, the animal remains a tadpole; once this relative concentration is exceeded, it becomes forcibly converted into an adult. By cutting out the thyroid, the tadpole phase is made permanent, and giant tadpoles, several years old, can be produced. By altering the amount of food and, consequently, the rate of growth, the time of transition is shifted. By adding iodine, the rate of production of the iodine-containing thyroid hormone is increased, and precocious metamorphosis results. By low temperatures, growth is favoured as against thyroid development, and the animals reach an unusually large size before they metamorphose. The main fact remains, namely, that there is a competition between two vital processes—the tadpole-producing processes on the one hand, the absolute and relative increase of the thyroid on the other, and that these are so timed by the inherited constitution that the latter catches up with and surpasses the former during development. It is probable that many other developmental processes have a similar basis. It will be seen that we are entering upon a new and interesting field of biological work—the chemical time-relations of development, which will be to biology what physical chemistry has been to chemistry at large.

It will not have escaped the notice of many of my hearers that the assumption of a specific "tadpole-determining" hormone, although a possibility, is not necessitated by the facts in the same way that the assumption of specific male and female-determining hormones are made necessary by experiments such as Minoura's on artificial free-martins in chicks. It is only necessary to think of one hormone, that of the thyroid, and two possible types of metabolism, one of which will occur when there is less than a certain relative amount of thyroid hormone, the other when there is more. Further, this explanation is equally applicable to cases such as that of sex in *Crepidula*—one type of metabolism leading to femaleness when there is less than a certain amount of the hormone secreted by the adult females, another leading to maleness when there is more.

That this is at least an alternative and equally fruitful way of regarding the facts, is shown by the recently published work of Bridges, again on the fruit-fly *Drosophila*. He discovered a strain which, by some abnormality of chromosome-mechanism, had become triploid—that is to say, it contained each chromosome in triplicate instead of in duplicate. By appropriate matings, it was found possible to obtain individuals which possessed either one, two, or three X-chromosomes in conjunction with three sets of autosomes, as the rest of the chromosomes are styled. It will be remembered that in a normal *Drosophila* two X's give a female, one X a male. In the triploid race, those with three X's gave females, those with one X gave abnormal males, and those with two X's were intersexes. It is thus clear that the determination of sex here is an affair of balance between the amount of a male-determining substance or substances, produced by the autosomes, and some other, female-determining, substance produced by the X chromosomes.

If we call the substance produced by the X-chromosomes χ , the autosomes A and the substance produced by them α , then a ratio of $1\chi : 1\alpha$ will give females ($3X : 3A$, or $2X : 2A$); a ratio of $1\chi : 2\alpha$ or more than 2α will give males ($1X : 2A$, or $1X : 3A$); and one of $1\chi : 1.5\alpha$ will give intersexes ($2X : 3A$). There is further evidence, of a nature too complicated to enter into here, that the "male-determining

substance" is not in reality simple, but depends upon a number of separate Mendelian factors scattered throughout the various chromosomes. In this case, it would be perfectly justifiable to say that there exist two types of metabolism, the one obtaining when there is less, the other when there is more than a certain relative amount of the "female-determining" substance contained in the X-chromosomes.

In any event, the work is of importance, because it shows that an intersexual condition may be produced by an accurate balance of male and female-determining substances, not necessarily by a switching-over from one sex to the other during development. We have therefore to distinguish "balanced intersexuality" as seen here, from "consecutive" or "developmental intersexuality" as seen in the Gipsy moth, *Gammarus*, etc. In other words, we have to distinguish two separate variables—first, the initial amounts of the male and

FIG. 8

female-determining factors in the inherited constitution, and secondly the different rates at which these produce male and female-determining substances during development.

Finally, another form of intersexuality, also found in *Drosophila*, must be mentioned. Sturtevant discovered a strain that was throwing intersexual forms; on analysis, it turned out that the abnormal condition was due to a mutation in a single Mendelian factor. All we can say at present is that this mutation in some way affected the metabolism so as to make it intermediate between the male and female types. It is of great importance, however, as proving that the most serious sexual abnormalities may be due to single mutations. In just

the same way, it appears probable that serious forms of feeble-mindedness in man may in certain cases be due, not directly to any defect of the hereditary constitution of the brain, but to a single mutation affecting the thyroid gland, and so indirectly the development of the brain.

In any case, the metabolism of male and female is often markedly distinct. This sex-difference of metabolism may be looked upon as the last stage in the chain of sex-determination. The hereditary factors are producing substances which lead to the production of male or female reproductive organs: these produce hormones which control other sexual characters, and interact with all the other ductless glands of the body; and this interaction results in a characteristic type of metabolism, different for male and female. It is, therefore, theoretically possible to alter the end-result—sex—by alteration of any of the links of the chain. One may alter the proportion or the rate of working of the hereditary factors, as in *Drosophila* and the Gipsy moth; or interfere with hormone-production, by castration, grafting, or possibly by acting upon other ductless glands; or finally, by acting upon the adult's metabolic processes. It is worth while insisting upon the existence of this chain, since its earlier links are often ignored by physiologists, its later links by zoologists.

As showing what fields for investigation are here opened up, I would like to mention a few facts illustrating the difference of metabolism which does exist between male and female of the same species. The blood of different species of insects, as in other groups of animals, often gives a precipitate when mixed with the blood of another species. A similar, often considerable, precipitate, is in many cases given when the blood of a male is mixed with that of a female insect of the same species. In *Drosophila*, the females hatch out before the males. When intersexes are present, their rate of development is intermediate. In the human species the basal metabolism of woman, when all corrections have been made for surface and weight, is less than that of man. In the Gipsy moth the whole metabolism is more active in males than in females, not only in the caterpillars at all ages, but also in the pupæ. To use the old terminology of Geddes and Thomson, the male is more katabolic, the female more anabolic. A somewhat similar sex-difference

exists in bees. The grub that is to produce a drone stores up glycogen and fat much more rapidly than the grub destined to produce a worker-female, and uses up these reserves much faster during the pupal period.

That an interference with metabolism may cause partial or total sex-reversal is shown by a number of facts. In the first place there exists the phenomenon known as parasitic castration, in which the presence of certain parasites re-acts upon the sexual characters of their host. This term is really a misnomer, since the atrophy of the reproductive organs is only one of the effects produced; "parasitic sex-modification" would be preferable. The best known example is that of the parasite *Sacculina*, which inhabits various species of crabs. Geoffrey Smith investigated very carefully the effects produced. He found that while in both sexes the reproductive organ was destroyed by the presence of the parasite, no other change was produced in the female, save that young females took on the female adult sex-characters more rapidly than normal. Parasitized males, however, gradually take on more and more of the female characters—their great claws grow smaller, their abdomen broader, their swimmerets enlarge and become fringed with the hairs to which in the female the eggs are attached. Most infected animals die; but in a few the parasite disappears, and the reproductive organs are then regenerated. Such animals, if females, regenerate a normal ovary. Males which have only been partially modified towards femaleness regenerate a normal testis; but those which had assumed full female sex-characters regenerate a reproductive organ in which both eggs and sperm are to be found, showing that their metabolism has been altered so that it has become actually intermediate between male and female. That the effects are not due to castration alone is obvious from the facts we have just mentioned. It is further definitely proved by what is known in insects, in which, as we have already seen, castration itself has no effect upon the remaining sex-characters; in other words, a sex-hormone is not produced by the reproductive organs, but, if it exists, by the body as a whole, under the direct influence of the sex-chromosomes in the cells of the various tissues. In spite, however, of this lack of dependence of sex-characters upon the reproductive organs, the presence

FIG. 9.—*Sacculina* and its effects on its host. (1) Diagram showing a *Sacculina* attached to the under side of the abdomen of a Shore Crab, with its roots ramifying in the body and limbs of its host. (After Delago). (2) 9) Spider Crabs, *Inachus dorsellensis*. (2) Normal male, (3) Under side of abdomen of normal male, showing copulatory styles. (4) Normal female. (5) Under side of abdomen of normal female, showing feathered appendages for carrying the eggs. (6) Sacculinized male. (7, 8) Under side of abdomen of two sacculinized males, showing reduction of copulatory styles and development of feathered appendages. (9) Under side of abdomen of sacculinized female, showing reduction of appendages.

of parasites may cause male insects to assume female sex-characters.

Finally, Smith showed that the crabs which harboured *Sacculina*, whether male or female, had circulating in their blood large amounts of certain fatty substances which in normal animals without the parasite only exist in the female sex.

Some very interesting work on fowls, as yet unpublished, which I am able to mention through the kindness of my friend, Dr. Crew, shows that in birds also sex may be influenced in this way. It has been known for some time that old hen birds of various species may assume male plumage. Crew has collected a number of such specimens in fowls. He finds that two separate groups can be distinguished. In one, the ovary is undergoing simple atrophy. These birds show a rapid assumption of male-type comb and wattles, a slow assumption of male plumage, but neutral behaviour. Similar results have been obtained by others by simple removal of the ovary, whose hormone thus normally prevents the development of certain of the male sex-characters. In the other group, however, the assumption of male plumage is much quicker, and the bird soon becomes almost indistinguishable from an ordinary cock. What is more, she (or he, or it!) begins to crow lustily, to fight with other cocks and to behave as a cock towards normal hens. In all such birds, the ovary has been found to be the seat of a tumour. There can be little doubt that the tumour is here playing a rôle very similar to that of a *Sacculina* in a crab, and is altering the whole internal environment of the creature so as to make it unfavourable for the persistence of the female organs and characters, favourable for the expression of the male characters, hitherto latent in the chromosomes. A few cases are on record where female birds which have assumed male plumage have actually developed spermatozoa in place of eggs in their reproductive organs. It remains to be seen whether, as is probable, this is the end-result of the changes produced by ovarian tumours. In any case, it is established that changes in metabolism, in the delicately-adjusted internal environment of higher animals, may produce profound alterations in sexual characters. The mere fact that sperm can be produced by a previously normal hen shows that the attainment of a stage in which sex-hormones are actively produced by the reproductive

organ need not prevent the ultimate reversal of sex; and they raise the interesting possibility that we may be able to find substances whose injection, even into the adult organism, may bring about a change of sex.

These fowls raise interesting questions for the psychologist. Here is an animal with a certain modicum of memory; it has been a hen, with the instincts and habits of a hen, all its life. Then comes a change of reproductive organ, a change of sex-hormone, and all its past appears to vanish, and to be superseded by totally new habits, which seem equally automatic of acquisition in old age as in youth. What has happened to the memories of the hen's life? It is at least a reminder of the degree to which mental processes and behaviour are under the control of chemical substances.

We must now turn to a special consideration of mammals and to man.

There is one subject which we have so far not dealt with—the seasonal variation in sex-ratio in various mammals. Statistics show that in Cuba, the seasons of highest birth-rate are those with lowest proportion of males, both in white and coloured people. If females are taken as 100, the difference in proportion of males is 104 as against 108 in whites, 99 as against 108 in negroes. Precisely similar figures are found for other mammals, although the difference may be far greater. In the greyhound, for instance, most young are born in the months March to June; the ratio of males to 100 females during these months varies from 113 to 119, while during the rest of the year, it varies from 128 to 195.

These results have received confirmation from the accurate work, carried out on pedigree stock under experimental conditions, of Miss King on rats. Her facts are seen at a glance in the accompanying curve.

FIG. 10.

There is further some evidence that sex-ratio differs with the age of the parents

the proportion of female children in man being greater when the mother is young. The old belief that war increases the proportion of males among offspring seems to find definite confirmation in the statistics recently published by Savorgnan (Metron, 1921). The increase, however, though definite and constant, is slight, amounting only to one per cent. or less.

The only evidence that large changes in the sex-ratio may be brought about in man is given by the recent and as yet unconfirmed work of Siegel (Münch: Med: Wochenschr: 1916), based on statistics collected during the war upon children conceived when their fathers were home on leave for short periods. Siegel finds a very marked correlation between the probable sex of the offspring and the time during the menstrual cycle at which impregnation and fertilization occurred. The diagram will give in condensed form the results of his investigation. It will be seen that children arising from an impregnation soon after menstruation (which is probably the period just before ovulation) are preponderantly males, while impregnation during the period from the 15th to 22nd day (probably the period just after ovulation) gives a large preponderance of females. The number of cases is small, but if the facts are accurate, the difference of sex-ratio undoubtedly exists.

Time of Impregnation (days after onset of menstruation)	Offspring.		% Males
	Male.	Female.	
1st--9th	37	7	84%
10th--14th	4	9	31%
15th--22nd	3	20	13%
23rd--28th	—	—	—
Total (80)	44	36	55%

Relation of Sex of Child to time of impregnation (man). (After Siegel.)

Siegel believes that this is due to different degrees of ripeness in the ovum, and fortifies his contention with the researches of Hertwig upon fertilization of over-ripe eggs in frogs. It should be borne in mind, however, that very little certainty has yet been reached as to the exact time during the menstrual cycle at which the human ovum is liberated. In any event,

the statistical results, so far as they go, are of the highest interest, and if they turn out to correspond with reality, will pave the way for a very large measure of practical sex-control in the human race—a serious matter, for if not properly regulated, it might bring about the most revolutionary social results.

There is, however, another possible theory to account for the facts. We have already seen that the male sex is often characterised by the possession of one chromosome less than the female, and that when this occurs, there will be two types of sperms, one with, the other without, an X-chromosome. Since it is the chromosomes which constitute the nucleus, and since the so-called "head" of a spermatozoon is simply a condensed nucleus, we might expect to find the difference in chromosome-number between the two sorts of sperm reflected in a difference in size of sperm-head. This is actually the case. In many insects, in the bull, the pig, the horse and other mammals, the two types can be readily distinguished. If a number of sperms of such animals are measured, they fall into two size-groups, while sperms with no chromosome difference show only one peak to their variation curve. When there are these two types of sperms, the large ones are female-determining, the small ones male-determining. From the available evidence, it is highly probable that spermatozoa of two sizes also exist in man.

Now if there are two types of spermatozoa, they may swim at different rates in their long adventurous journey to find the ovum in the upper recesses of the Fallopian tube, or they may be of differing susceptibility to various agencies. Further, it is more than possible that the conditions for their journey within the body of the female may vary considerably at different times of the menstrual cycle; and if this is so, the female-determining sperms might well be favoured at one time, the male-determining at another. Here again there is a large field for experiment.

In plants, it has already been shown by Renner and others that pollen grains containing different hereditary factors may differ in their rate of growth from the pistil to the ovules; and in the Campion, where there are known to be male and female-determining pollen grains, Correns has shown that these have different growth-rates, and that the difference may be increased or decreased

by various circumstances, giving rise to differences in sex-ratio. In animals, there is evidence that the female-determining spermatozoa (in guinea-pigs) are more susceptible to the effects of a poison such as alcohol than are the male-determining.

If Siegel's results cannot be interpreted on the assumption that the difference in sex-ratio is due to differing susceptibility or activity of the two sorts of spermatozoa, then it is very difficult to understand why there are not very frequent exceptions to the rules of sex-linked inheritance in man. But, as a matter of fact, these pursue their normal course. One of our previous diagrams shows the pedigree of a family in which haemophilia is prevalent. As will be seen, the disease is transmitted through females, appears in males and from them passes to their daughters only; this, of course, is what would be expected if the disease was due to a recessive factor lodged in the sex-chromosome, and if women were XX in constitution, men X or XY. Exceptions to this rule do occur, in animals as in man, but they are very rare. In any case, the fact of the existence of different-sized male and female determining spermatozoa in mammals opens up all kinds of possibilities. It should prove possible to separate the two kinds artificially, and then, by means of artificial insemination, to control the sex of the offspring.

There remains the possibility that in mammals, as in moths and frogs, occasionally individuals which have the chromosome formula of one sex may be converted into functional individuals of the other sex. If this is so, they should, as we have seen, give an abnormal sex-ratio in their offspring. If they are XX individuals functioning as males, their children should be all females, if the reverse, their children should be 66% males. Statistics could here be called to our aid. An analysis of the sex-ratio among the parents and offspring of families consisting entirely of one sex is needed. Similarly, if the slight increase in the proportion of males consequent upon the war be due to such a sex-reversal, then there should be a corresponding increase of females in the next generation, some twenty to forty years hence.

There can be no doubt, however, that partial sex-reversal in man may and does take place, leading to the production of intersexes (usually referred to in the medical literature as pseudo-hermaphrodites). New

light is thrown upon this dark medico-legal subject by the biological conception of intersexuality. Both when intersexuality is caused by hormones, as in the free-martin, or when it is caused by the blending of unbalanced sex-factors, as in the Gipsy moth, all stages are to be found in the conversion of one sex into the other. Thus, even when a human intersex is predominantly male, it (as we had better provisionally style the intersex) may have started as a female. The study of human intersexes is beset with the greatest difficulty. They may be due in some cases to the failure of the mechanism which normally prevents male embryos from being affected by their mothers' female-determining hormone; or (most probable explanation) they may be due to the combination of mal-adjusted sex-factors, or to a single Mendelian mutation.

It is important to note that a complete transition exists in man from very slight degrees of intersexuality, where only the sexual instincts seem to be affected (and here it is interesting to find that most modern authorities hold that most cases of sexual perversion are due to inherited causes) through advancing degrees of so-called pseudo-hermaphroditism, in which various stages of physical intersexuality occur, to complete hermaphrodites. This complete transition is paralleled by the transition in Goldschmidt's moths.

It is not only perfectly possible, but even probable, that mal-adjusted sex-factors may exist in man as in moths; but the end-result will not be the same in man, because of the existence of the hormone produced by the reproductive organs. It is probable that a relative excess, say, of female-determining factor in a male embryo, would lead to a condition in which the reproductive organ was slightly intermediate at the time when it began producing its hormone, and that this intermediate or intersexual condition would, by means of the hormone, be maintained at the same level throughout life.

Several results follow from such a consideration of human sexual abnormality. The first is therapeutic: there is a distinct theoretical possibility that cases of sexual perversion might be cured by injection or grafting of the proper reproductive organ. Goldschmidt has already drawn attention to this, and I believe that the suggestion is being tested in Germany. The second is legal: it is highly probable that human intersexes

are neither male nor female, but definitely intermediate in sex. If so, then it must be wrong to assign a normal sex to them legally, for they belong to a third category, and if this category is biologically a real one, as is certainly the intersexual category in moths, then the law should recognize it. The third is ethical: we are accustomed to visit departures from sexual normality with legal penalty and moral censure. If, as seems highly probable, many of the individuals who thus depart from the normal are not morally perverted, but simply in the grip of blind hereditary forces, of whose results alone they are aware, then it is clear that a new standard is needed with which to measure the whole matter.

In conclusion, I may remind my hearers that twenty years ago we knew nothing whatever of any of the chief facts which I have dealt with in this lecture. In that short period we have, as I hope I have been able to show you, gained definite information on many of the links of the causal chain determining sex. Many workers, it is true, had advanced views often similar to those I have laid before you; but these were the result of guesses, even if of inspired guesses. The causal mechanism was still unknown; and, as Bacon put it once and for all, *vere scire est per causas scire*.

The difference between the sex-chromosomes of polar body and egg in moths and birds; the differences between male-determining and female-determining sperms in some insects and in mammals; the differing rates of working of the sex-factors in different geographical races; the existence and method of working of sex-hormones, particularly in mammals; the difference between male and female metabolism; in all these fields we are at last in possession of definite facts, and facts which, in the long run, are bound to lead to practical control. Scientifically staffed institutions, where theory may join hands with practice, will accomplish for animal breeding, and for eugenics, what the works laboratory and the research association are doing for applied chemistry. Knowledge is, in the long run, always power. If you are convinced of this, and if I have convinced you of the rate at which our knowledge of this particular problem is growing, I shall be content.

I wish to end this lecture by making three appeals. They are for the recognition of biology on an equal footing with chemistry

and physics, on the one hand as an exact science; on the other, as an indispensable pillar of modern civilization. Physiology during the last half-century has applied increasingly exact methods to certain biological phenomena, but study of the most fundamental processes of life has scarcely passed beyond the observational stage. By fundamental processes I mean those in which living units—whole organisms—are concerned; processes which are to the last degree complex from the standpoint of inorganic chemistry and physics, but are unitary and simple from the standpoint of biology as a science of organisms.

I should include, under this head, in the first place, the physiology of whole adult organisms; this is largely a study of organic regulation. The realization of the function of the ductless glands, of the protective reactions of the blood and tissues; the analysis of the working of the central and sympathetic nervous systems, were necessary before even an idea of the gross regulation of a vertebrate's life-processes could be formulated. Before what we may call the microscopic analysis of these processes can be attempted, a considerable study must be made of enzymes, of the colloid state, of bio-chemistry in the narrower sense, of immunity reactions.

It could not begin to progress until after the functions of ductless glands were realized, and is yet in its infancy.

Secondly, the physiology of development—the study of the changes by which the simple ovum, passing through forms of greater and greater complexity, becomes converted into the adult; the study of regeneration, of budding, of developmental reversal and regression. This is largely a study of the regulation of form. Forty years ago this field was scarcely touched. To-day we have reached certain broad principles in regeneration and experimental embryology, we have been introduced to new horizons by the study of artificial parthenogenesis and of tissue culture, we have amassed a multitude of facts. But the complexity of the subject is even greater than that of adult physiology, and the unifying principles needed to correlate the various facts even more to seek.

In the third place, there is the study of heredity, which in its turn is mainly a study of the regulation of species—their constancy and their power of adaptation. On the one hand, the discovery and detailed

study of the chromosomes, which in its turn depended on the perfection of microscopic technique; on the other, the discovery that the hereditary constitution was composed of separate factors united in definite relations of proportion and place; these, together with the discovery of mutation in the factors, were needed before the study of heredity could become in any sense scientific.

Fourthly, we have the study of organic evolution—the regulation of life in its totality. The study of fossils, of geographical distribution, of variation, of adaptation has opened a window here and there to our ignorance, but we can scarcely be said to have advanced materially in our views of evolution since Darwin's day. The laws of the genesis of species, the study of natural selection, the succession of types, the whole concept of biological progress—all these subjects await the vivifying touch of the experimentalist and the mathematician.

What I am here concerned to point out is first that the prolegomena of an accurate biology are all biological—ductless glands, colloids, enzymes, chromosomes, nervous regulation, and the rest. Physics and chemistry would not have led on to their discovery and intensive study; but biology has opened up whole new fields in which the methods and the knowledge we already possess of physics and chemistry can now profitably be employed.

Biophysics and biochemistry will, as time goes on, afford the most interesting and intricate problems for the physicist and the chemist. My appeal is partly to the chemists and physicists, that they may realise the exactitude to which biology is tending, the part she can play in presenting them with problems of unsurpassed interest, the duty they have towards her.

It is secondly to the representatives of scientific medicine. There is at present in this country a tendency for medical research to become more and more biological. This is in itself a wholly admirable tendency; but it is dangerous in so far as it induces biology to become more and more medical. Through its power and practical importance medicine can establish a medical point of view in biological thought; and the medical point of view is in the nature of things narrower than the biological. It is through the study of biologists upon flies that new vistas in heredity have been opened up by the establishment of the chromosome

theory; by their work upon moths, as we have seen to-day, that wholly new ideas upon sex have been reached; by their experiments upon *Amphibia* that new accuracy and new speed have been introduced into the study of the effects of the ductless glands. The medical point of view must inevitably be dominated by the study of human and mammalian physiology; pure biology, busy with nature's myriad types, must continually be lighting upon more favourable material, upon new points of view.

Finally, my appeal is directed to the general public, and especially to that part of it which is concerned in the shaping of opinion and of policy; it is an appeal to realise the importance of biology to national and general civilisation and progress. Pasteur's work on spontaneous generation led to the foundation of the whole science of bacteriology; Metchnikoff's observation of phagocytes in a starfish larva provided the impetus to great advances in the study of immunity; the desire of Mendel, of Bateson, of Baur, of Morgan to comprehend the nature of heredity has laid the basis of new methods of animal breeding, and given us hope that Eugenics may become a matter of practical politics; the debt of medicine to physiology is a commonplace, but none the less vast for that.

The work now being done at Rothamsted and elsewhere upon the bacteria of the soil is bound to lead to improvements in agriculture, while the science of bacteriology has revealed various chemical aptitudes of micro-organisms which may be of the greatest practical utility to man in his attempts to synthesize useful substances.

The pure desire for knowledge, the pure pleasure in discovery, will always contribute its share to results of practical importance, to essential progress; together with the direct desire to achieve a definite practical result. Judging by the facts of history, it will continue to contribute the larger share.

There will never be a lack in this country of those who are eager to carry on the work of discovery for its own sake; but the technical difficulties in the way of progress increase with progress itself, in biology equally with chemistry or physics. The keeping of animals, and especially the breeding of them on a large scale is expensive and often difficult; the education of good biologists is lengthy and costly; the number of different techniques which are needed to

bring a large biological problem to a conclusion is very great.

Chemistry and physics are the agencies by which we obtain control over our lifeless environment. Biology, in its widest sense, is the agency by which we obtain control over life, our own life included. I see many signs that the older divisions of biology are melting away. Physiologists are turning more towards the lower animals; zoologists are supplementing the methods of comparative anatomy by those of physiology; the geneticists are confounding botany and zoology in their single science. Everything points to the reintegration of a science of pure biology. And it is for a fuller recognition and appreciation of this science that I plead.

[Figures 1, 2, 4, 7 and 9 are taken, by permission, from "The Determination of Sex," by L. Doncaster, Sc.D. (Cambridge: at the University Press, 1914); and Figures 3, 5 and 6 from "Mechanismus und Physiologie der Geschlechtsbestimmung," by Prof. Dr. Richard Goldschmidt, Mitglied des Kaiser - Wilhelm - Instituts für Biologie, Berlin - Dahlem. (Berlin: Verlag von Gebrüder Borntraeger, 1920). For further information reference should be made to the above named general text-books.]

DISCUSSION.

The CHAIRMAN (Dr. Chalmers Mitchell) said he was afraid if any had come to hear the extraordinarily interesting paper Mr Huxley had read with the idea that they would go away with a receipt for determining the sex of their next baby, or whether they were going to have more male or female calves in their farmyard stock, they would be disappointed. On the other hand, if they had followed even a portion only of the extremely interesting though complicated facts the lecturer had placed before them, they must realise that although, at the moment, science was not able to give practical results of that kind, it was rapidly approaching a stage when that might be possible. He would like to give one or two reasons, gathered from the lecturer's remarks, in support of that possibility. It appeared to be the case that the primary distinction of sex—the possession of the male or female reproductive organs—depended on the presence in the sexual cells of a particular enzyme, a particular ferment or chemical material which, in all probability, was stored up in the odd chromosome known as the X chromosome. While on that point, there was one criticism he wished to make. In so fundamental a thing as sex—a thing that went right back to almost the lowest known

organisms—he would be, *a priori*, rather surprised to find that there were different ways of determining it. He found it very difficult to believe, for instance, that birds and moths determined it through the female while mammals and some insects determined it through the male. One would expect so fundamental a distinction, which had existed from the very beginning of the living world, to work right through by more or less the same mechanism and to obey the same laws throughout the animal kingdom. It was exceedingly rash, he was well aware, to raise an *a priori* objection in biological questions, because so many strange things were being discovered that one was liable to go wrong. It appeared to be the case that the primary distinction of sex was determined at the time of fertilisation, and that the mechanism was so adjusted that under normal conditions on the average there would be an equal proportion of males and females. It had been clearly shown, however, that that equal ratio of male and female could be altered experimentally in certain cases—in some by an alteration of temperature, in others by retarding the time at which the egg was fertilised; so that, right at the beginning, there was definite experimental evidence that one could control, in certain cases at least, whether the ratio was to be equal or to dip towards one side or the other. Once the primary distinction between the sexes was determined, internal secretions or hormones were liberated which began to control the other characters of the body—not merely the primary sexual characters, but all the other characters associated with sex. Then, again, it seemed to be definitely proved that the rate at which the male-determining hormone or the female-determining hormone developed varied with conditions which were subject to experiment and could therefore be altered, so that not only primary but apparently secondary sexual characters were subject to experimental change of the natural ratio. There was a very great difference between the primary sexual characters and all those secondary sexual characters, and it certainly did not seem to follow that although one was able to change the secondary sexual characters one was going to make any difference to the primary sexual characters. He gathered that in the case of insects there was practically no relation between the primary and secondary sexual characters, whereas in vertebrates there was a very definite relation between them. That seemed to show that in the case of individuals which were neither male nor female, but partly each, and which were known by the rather awkward name of "intersexes," there were two entirely different things to disentangle. There was the possible transformation of the primary reproductive organ of one sex into that of the other, or—as seemed more probable—the replacement of one by the other. The alteration of the secondary sexual

characters was an entirely different matter. When dealing with the very difficult and interesting question of "intersexes" to which the lecturer had alluded, it had to be borne in mind that the idea was by no means so new as the Mendelians appeared to think. It was many years since the famous Danish naturalist Steenstrup, of Copenhagen, first propounded the theory that sex was distributed all over the body, and in different proportions in different individuals, and that, quite apart from the primary sexual character, there were those secondary sexual characters mingled throughout. A little later, but before any of the recent work (which had, he thought, been a little over-emphasised), a German named Otto Weininger wrote a very elaborate book on sex, in which he worked out at great length the relation of internal secretions to the primary maleness or femaleness of the different parts of the body, and discussed at considerable length a number of problems which modern workers were now submitting as entirely new discoveries of the Mendelians. He thought the work of the Mendelians was of very great interest, and might lead in the future to results of great importance. All those who had heard Mr. Huxley's paper that evening must be greatly indebted to him for it, but personally he hoped people would not go away with the idea that an entirely new line of discovery had been opened up and that the world was going to be transformed, the criminal law amended and many other things happen simply because some flies had red and some had white eyes, and because they behaved curiously in bottles in American laboratories.

MRS. R. HAIG THOMAS said she had carried out a number of experiments in breeding pheasants, and in nearly every case it had been found that the female offspring followed, both with regard to their primary and secondary sexual character, the characters of their father's mother.

DR. L. T. HOGGEN said the Chairman had mentioned that he found difficulty in attributing to birds and moths a different method of sex determination from that which obtained in the case of the majority of other animals investigated. But, if he might amplify a point which had been already made by the lecturer, it must not be imagined that the evidence regarding the difference in the method of sex determination between moths and birds on the one hand and men and flies on the other was obtained solely by examination with the microscope: it could be deduced from the facts of sex inheritance, from breeding experiments, quite independently of any microscopic data. Moreover, whether those results were represented by means of the elaborate Mendelian nomenclature or not, the fact that certain characteris-

tics existed in birds which the female could only transmit to her sons did indicate the existence of two kinds of ova, while the fact that certain characteristics existed in flies and man which the male could only transmit to his daughters did indicate, apart from microscopic evidence, that there were two types of sperm produced. Under those circumstances, he did not think it was fair to raise an *a priori* objection.

DR. M. J. ROWLAND asked whether there was any truth, and, if so, what was the reason for it, in the popular belief that, after a period of warfare, there was an increase in the number of males born as compared with females. Could it be ascribed to lack of proper food? As a large breeder, breeding some 2,000 animals a year, he had recently been experimenting with the question of vitamins, and had found they had a marked effect on the prolificness of an animal. In the case of a herd of pedigree middle white pigs, the average litter, with ordinary feeding, consisted of about seven animals; but at the present time, after feeding with the three vitamins, the litters had attained such a size that it was felt unwise to proceed further; nineteens and twenties, and even twenty-ones, were quite common. Some time ago he purchased a number of pigs, in order to test his theory, from people who had kept them, according to the old filthy custom, in styres. He tested the food those animals had been getting, and found it deficient both in fat-soluble and water-soluble vitamins. They were having litters of three, four or five. Whether it was due to better class feeding generally or the presence of vitamins in the food it was impossible to say, but he was already getting litters of fourteen and fifteen.

MR. G. C. ROBSON said he had been informed by various breeders of pigs that the statement the lecturer had made with regard to the time of fertilisation also held good with regard to those animals. He believed, also, it had been found by Pearl and Parshley to hold good in the case of domestic cattle. In his very able book on the determination of sex, Doncaster laid down the generalisation that in some cases the sex ratio was exclusively determined by the composition of the gametes, but that in other cases, where the organism might be said to be in a more unstable physiological condition (chromosome differences between the sexes being slighter) it might be regarded as being more susceptible to environmental factors. That was written eight years ago, and he would like to know whether Mr. Huxley regarded it as shaken in any way by modern experimental work.

MR. G. W. OVERMAN said he had attended the meeting that evening in the hope of adding to the little knowledge he had gained by ex-

perience with horses and cows. He had been studying the problems connected with the breeding of horses and cows for the past twenty years, and he had proved that sex followed sex. If a cow had a heifer calf to-day and was mated next time mating commenced she would have a heifer calf again, but if she was passed over she would have a male calf. The same was true of horses. What he had said was true of cross-breeds; he did not know whether it would apply to pure bred animals. His system very rarely failed, and he would be interested to know if anyone else present had tried it. Mr. Spencer, a friend of his (Mr. Overman's) father, read a paper forty years ago to the Board of Agriculture on the same subject. He himself had been taught the system by his father about forty years ago. He had had a cow which dropped four heifer calves; three of them lived and all three bred. Was that usual when there were so many females? He knew when there was a male and a female the female did not breed, and thought it rather unusual for all three calves, born under the circumstances he had mentioned, to breed.

MR. HUXLEY said there would be no difficulty in that.

MRS. M. HUNTER said she was only a very small breeder, but had been breeding pedigree Jersey cattle for the last six years. About four years ago she heard of the system the last speaker had described, and since then had followed the same methods with the same excellent results; she had always had heifer calves when she wanted them.

DR. H. CORNER said that to a certain extent he also was a breeder of cattle and other stock, and had, in a small way, tried the same experiment as the two speakers who had preceded him, but he was not quite so enthusiastic about it as they were. The first time he tried it he was very successful, but latterly it had not worked so regularly. Everyone present was probably familiar with the work of Mr. Bonhote with regard to the determination of sex. That gentleman found by experiment that with a reduction of vigour he got many more males and with high vigour many more females, and his own experience supported that contention. It was well known, in the case of cattle, that the old cows threw bulls. Old cows, of course, were beginning to fail in vigour, and therefore should throw males according to Mr. Bonhote's theory. There was a great deal of evidence, into which he could not go that evening, to show that the female required much more vigour for the development of her femaleness than did the male for his maleness. One of the difficulties met with by those breeders who were aiming at high milk records was that when the cow was exhausted by that process she threw

bulls. With regard to sex-linked characters, so called, if those characters were sex-linked they should be always sex-linked, but they were not. It had been clearly shown that characters which were supposed to be sex-linked could be produced in the opposite sex by the reduction of the vigour of the parents. Mr. Bonhote had shown that. It was Miss Wilde, he believed, who had become famous through producing the male tortoise-shell cat, a great rarity. That had been done through in-breeding and reducing the vigour. The same was done with pigeons. Fanciers who wanted to show a silver male, for example, bred a blue cock to the silver hen; from the progeny they selected a blue son which carried the dominant, and they bred back the hybrid blue son to its own mother. Mr. Bonhote had definitely proved that Mendelism did not hold good in such cases; he had experimented with rats and succeeded in effacing the dominant. He had recently been studying the inheritance of high production in dairy cattle, which is transmitted through the male and appears in the female, and his explanation was that the high-producing cow had her vigour reduced, first by the development of her femaleness, and subsequently by her excessive lactation, the result being that the daughters of high-producing cows were only moderate dairy cattle, as they had not enough inherited vigour to be able to express that quality, while their sons transmitted "high production" because the development of their maleness used up less vigour and so left more vigour for the development of other qualities. Cattle, being mammals, should, according to the lecturer, transmit their "sex-linked" characters through the female and those should appear in the male, but this is contrary to the experience of all breeders of dairy cattle. The tortoise-shell cat already referred to was another example of a character (tortoise-shell) being transmitted through the male and appearing in the female, and it would be interesting to know whether the chromosomes in cattle and cats differed from those in other mammals and were the same as those found in birds and moths.

MRS. A. SOAMES said she was a breeder of goats on a large scale, and got an enormous number of hermaphrodites. She would like to know the reason; was it due to tremendous in-breeding? She had been told that goats were the only animals affected in that way.

MR. HUXLEY, in reply, said the point raised by the last speaker was of great interest. Hermaphroditism did occur with goats, and seemed to be of the same nature as intersexuality in moths. The question of vigour in cattle or other animals was an exceedingly difficult one, because it was hard to measure vigour; it was largely a matter of opinion. With regard to the question of producing one

sex continuously by always utilising the immediately-following period, he thought all scientists would welcome detailed figures on the subject. Practical breeders did not always, he thought, realise the need for detailed figures. It was necessary to have large figures before one could exclude the possibility of chance, and if practical breeders wished to do a great service both to breeding and to the science of genetics they should collect detailed figures of sex relative to age of cattle and goats, relative to vigour (if they could give any details), to time of service and so forth, and send them to such people as Professor Bateson, of the John Innes Institute. He knew, also, that the gentleman who edited the *Journal of Genetics* would welcome them. It was true, as Dr. Rowland had suggested, that there was an increase in the proportion of males born after a period of war. The increase was very slight—about 1%—but, curiously enough, it did not occur in all those countries which had suffered privations on account of the war. It was difficult to understand the reason.

Finally, if he might reply to the Chairman's criticism, he did not wish to claim any extraordinary novelty for the ideas he had set out. He thought the real distinction between the pre-Mendelian school and those who came after them was that while the former doubtless had an intuition of reality, people nowadays, for the first time, actually saw and knew the mechanism which was working to produce the observed results, and to find out a mechanism was eventually to control its workings.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Huxley for his paper. The proceedings then terminated.

NOTES ON BOOKS.

ATOMIC THEORIES.—By F. H. Loring. London: Methuen and Co., Ltd., 1921. 12s. 6d. net

In these days of consideration for the pounds, shillings and pence, we may perhaps be excused for noting with satisfaction that the price for a work of the present scale, scope and quality, is low if measured by to-day's rates; a fact which gives ground for congratulation to the publishers, and which may afford good augury as regards the prices of the higher grade books in the near future. The present book consists of 218 + X. large octavo pages, with 66 figures in the text, and the price is 12/6 net.

Our feeling of satisfaction at the lowness of price implies a somewhat hearty approval of Mr. Loring's work, as an unsatisfactory book is dear even at a low price. The author takes his readers faithfully and well through the difficult and narrow way of recent research and speculation as regards atomic constitution, and in turning over the pages a first impression

of the reader will be a sentiment of satisfaction at the large amount of detail as to recent aspects and researches.

Study of the Kinetic theory of gases (p.3) is a good introduction, and it is pointed out in what sense the four gas laws may be inexact: disturbances arising which may perhaps be termed "inter-gravitational," for want of a better term.

This study may lead us towards the old argument of Wollaston (Daubeny on the atomic theory, 2nd. edition, Oxford, 1850 p. 125) that if the constitution of the gases is atomic there should be a limit to our atmosphere, a sentiment in general accord with our author's 2nd. chapter (p.8) in which we find a short but lucid account of Sir J. J. Thomson's method of recording the single impact of an atomic mass on a photographic plate and plotting out dotted lines or curves by sequent impacts. This method of research opens out new vistas (p. 8 to 14) as to estimating masses, and by improvements due to Aston certain atomic masses have been estimated with a conjectural accuracy of about one part in a thousand.

The details of this surprising progress in the study of the nature of matter are lucidly, sequently, and exactly indicated in Mr. Loring's remarkable book, but we may perhaps attempt to give our readers a faint concept of the principles which underlie the means by which the relative weights or masses of individual atoms or molecules may be estimated, even in a mixture containing masses of varying magnitude; and it is conceivable that developments of this method may ultimately lead to the automatic plotting out in graphic form of all the relative weight of the atomic masses and also the relative proportions. In this spirit we may dream until we imagine all the elements automatically recording or charting their own characteristics in number, measure, weight, and relative proportion.

Imagine a high attenuation in a vacuum apparatus and atomic masses flying off in random directions, while a long narrow tube serves to sort out such particles as fly in one direction. By virtue of the electric charge or associate electron, each particle, atom or quasi-atom may, under proper conditions, imprint a minute developable spot on a photographic plate: this making it possible to obtain a time record as to the incidence of each mass as it impinges upon a traversing sensitive surface. Let us now suppose a stream or sequence of individual atoms emerging from the outer end of the long narrow tube, and on this stream an electro-magnetic field or other like deflecting agency is brought into play. It is obvious that the constituent atoms of the stream may thus be sorted out according to their responsivity to the deflecting influence. Appropriate arrangements of deflecting agency

and sensitive plate may so order things that similarly deflected atoms form curved tracks on the plate and from these tracks rather full data may be calculated, especially when the responsiveness to the deflecting agency is a function of mass. A remarkable vista of ultimate progress thus suggests itself, in the shape of a photographic plate covered with dotted curves each being produced by particles of like mass. Towards this aim much has been realised, as will be evident to any one who reads Mr. Loring's work.

One immediate result, as recorded in the second chapter, is that good reason is found for the conjecture that some of our "elements" ("*quoud nos* Elements," to use the term adopted by Dr. Daubeny to avoid such verbal solecisms as compound atom, or compound element, see p. 428 of his 2nd. edition of 1850, mentioned above) are compound in the sense of being composed of constituents which differ in atomic weight or mass by whole numbers, and that it is the mixture of these whole number isotopes (Soddy uses the term iso-tope as indicating that they occupy the same field or locality in the periodic system) which gives rise to some, many, or perhaps all of the departures from Prout's law of whole numbers: hydrogen, however, appears to stand isolated in this respect.

It is impossible even to hint at all of Mr. Loring's many co-ordinated matters, but we may mention dicta as to the nature of light-emission, the Zeeman effect, and inter-atomic spaces being apparently related to the planetary distances; also we may mention one figure or parable given by Mr. Loring to aid the imagination in forming a concept of the starry heavens in miniature. Our author tells us (p. 82) to suppose the whole starry heavens as seen by man to be proportionally reduced until contained in an ordinary room. and then the individual units would be as invisible as are the molecules in air.

The octet theory which follows is based on an attempt to apply the recognised laws of electrical attraction and repulsion to the study of the stable equilibrium of particles, and the conclusion is that atoms generally possess a property that may be more or less indicated by the similitude "cubic symmetry," and it may be noticed that the graphic formula of pyrophosphoric acid as represented on page 109, according to the octet theory, rather recalls the graphic notation of Crum Brown, as adopted by Frankland in his lecture notes for chemical students, London, 1866: but the figurative units of Crum Brown are spherical, while those of the octet theory are cubical.

If reference is made to Dr. Daubeny's work mentioned above, it will be seen that the atomic theories of Leucippus, and also his cosmogony (p. 12) have an interesting parity with what is stated by Mr. Loring as to atomic energies; also distances in relation to the heavenly bodies

and their orbital conditions; while in the Pythagorean doctrine of numbers (p. 29) there is some germ of the octet idea: indeed this octet view runs more or less through the writings of the atomists of ancient times. Dr. Daubeny in the work which we mention, gives a very good summary of ancient views on atomism; mainly Indian, Greek, and Roman. As the many merits of Mr. Loring's book make it probable that in a sequence of editions it will become the standard work on atomic theories, it may be well for the author to re-consider and revise his account (p. 1) of the views said to be attributed to Democritus: possibly in some Greek play intended to burlesque the views of the atomists who in Athens were popularly held to be heterodox by reason of their teachings as to the revolutions of the heavenly bodies, and their rejection of the anthropomorphic deities of Greek mythology.

Dr. Daubeny (p. 462 of his 1850 edition) gives high praise to Democritus as one who set the example of questioning nature by experiment and refers to Bacon's eulogium of Democritus with respect to his profound acquaintance with physical Science, and mention is made of the way he was "ridiculed by the vulgar," e.g. in Athens. In short, as present-day investigations have made the atomic theory almost a reality, it is expedient that future editions and other works on the subject should be prefaced by connected notes on the views held in ancient times. Dr. Daubeny's book represents good work and scholarship up to the date of its publication, and something has been done since by French chemists. One great difficulty is to attach correct meanings to the terms used in the older writings, especially those of Athens in the period of Pericles and subsequently

GENERAL NOTES

CHEESE PRODUCTION IN GREECE.—According to a report by the U.S. Vice-Consul at Athens, the cheese production of Greece for 1920-21 is 30 per cent. less than for 1919-20 on account of lack of pasture, the winter having been mild and snowfall insufficient. The production of cheese has been: Casseri cheese, 4,252,250 pounds in 1920 and 2,962,575 pounds in 1921; macaroni cheese, 9,875,250 pounds in 1920 and 6,912,675 pounds in 1921; cheese sliced in brine, 8,464,500 pounds in 1920 and 4,937,625 pounds in 1921. This year the sale of cheese is not subject to Government regulation. Market prices per oke (1 oke = 2.82 pounds) are as follows:—Macaroni cheese, wholesale, 10.40 drachmas (1 drachma = about 3½d. at present exchange), retail, 12 drachmas; casseri cheese, wholesale, 12 drachmas, retail, 13.20 drachmas; cheese sliced in brine, wholesale 7 drachmas; retail, 8 drachmas.

BRAZILIAN CENTENARY EXHIBITION.—The prospects of this exhibition, which will be held from September 7th to December 22nd, are reported to be excellent. The site offered for the British Section is, according to the "Board of Trade Journal," among the finest in the whole exhibition area, and the local arrangements are in the hands of a Committee, of which H.M. Ambassador, Sir John Tilley, is president. On the 28th December the Governor of the Federal State (Dr. Carlos Sampaio) laid the foundation stone of the central permanent pavilion, which it is intended to present to the Brazilian Government as a memorial of the occasion at the close of the exhibition. Although the present state of Brazilian exchange militates against the hope of immediate business on a large scale, British traders, it is pointed out, cannot ignore the Brazilian market, which offers special attractions in certain clearly defined lines. The Brazilian people are said to be strongly predisposed in favour of British firms and British goods. The British capital invested in the country, exclusive of that invested in banks, shipping and telegraphs, aggregates to no less than £250,000,000 sterling.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, FEBRUARY 6. Health, People's League of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Dr. B. Hart, "Primitive Instinct."
Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Dr. A. T. Schofield, "Difficulties of Evolution."
Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. T. J. Guericke, Presidential Address.
Chemical Industry, Society of, at the Chemical Society, Burlington House, W., 8 p.m.
Surveyors' Institution, 12, Great George Street, S.W., 8 p.m.
Geographical Society, Eolian Hall, New Bond Street, W., 8.30 p.m.
British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. President's Address to Students, and presentation of prizes.
Royal Institution, Albemarle Street, W., 5 p.m. General Meeting.
Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal Meeting.) Mr. J. Joseph, "Some Practical Applications of the Thermionic Valve."

TUESDAY, FEBRUARY 7. Royal Institution, Albemarle Street, W., 3 p.m. Prof. H. H. Turner, "Variable Stars." (Lecture II.)
Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.
Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Col. T. C. Hodson, "The Primitive Culture of India." (Lecture III.)
Zoological Society, Regent's Park, N.W., 5.30 p.m.
1. The Secretary's Report on the Additions made to the Society's Menagerie during the months of November and December, 1921.
2. Mr. A. H. Evans, "Some Deductions from a Set of Cuckoo's Eggs taken near Cambridge, and now exhibited." 3. Lord Clifford of Chudleigh, "On *Nototherium Mitchellii*." 4. Miss L. E. Cheesman, (a) "Sense-organs of the Fresh-water Crab *Cardisoma armatum*," (b) "Position and Function of the Syphon in the Amphibious Mollusc *Ampullaria Vermiformis*." 5. Mr. C. W. Hobley, "The Fauna of East Africa and its Future." 6. Dr. J. Stephenson, "Contribution to the Morphology, Classification, and Zoogeography of Indian Oligochaeta." 7. V. On the diffuse Production of Sexual Cells

in a Species of *Chaetogaster* (Fam. Naididae).
V. On *Drauidia japonica* (Michlan.), a Contribution to the Anatomy of the Moniligastridae.
VI. On the Relationship of the Genera of Moniligastridae; with some Considerations on the Origin of Terrestrial Oligochaeta.
Marine Engineers, Institute of, 85, The Minories, Tower Hill, E., 6.30 p.m. Mr. R. W. Robinson, "Combined Internal Combustion and Compressed Air Engine."
Alpine Club, 23, Saville Row, W., 8.30 p.m. Mr. T. H. Somerville, "Five Weeks of Good Weather in 1921."
Electrical Engineers, Institution of (N. Western Section), 17, Albert Square, Manchester, 7 p.m. Messrs. L. J. Romero and J. B. Palmer, "The Interconnection of A. C. Power Stations."

WEDNESDAY, FEBRUARY 8. Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m.
Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m. Professional Lecture.
Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Mr. W. Doderet, "Racial Types in the Bombay Presidency."
Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Dr. L. Cobbett, "The Role of the Three Types of Tubercle Bacilli in Human and Animal Tuberculosis."
Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Prof. A. W. Kirkaldy, "Industrial Unrest: Does it make for Progress?"
Automobile Engineers, Institution of, at the Institutions for Mechanical Engineers, Storey Gate, S.W., 8 p.m. Mr. E. L. Bass, "Engine Lubrication."

THURSDAY, FEBRUARY 9. Royal Institution, Albemarle Street, W., 3 p.m. Sir Napier Shaw, "Droughts and Floods." (Lecture II.)
Historical Society, 22, Russell Square, W.C., 5 p.m. Anniversary Meeting. Address by the President, the Hon. J. W. Fortescue.
Central Asian Society, at the Royal United Service Institution, Whitehall, S.W., 5 p.m.
Optical Society, at the Imperial College of Science, South Kensington, S.W., 7.30 p.m. Annual General Meeting.
Metals, Institute of, Technical Institute, Jewry Street, E.C., 8 p.m. Mr. R. T. Rolfe, "Gun Metal."
Antiquaries, Society of, Burlington House, W., 8.30 p.m.
Royal Society, Burlington House, W., 4.30 p.m.
Chemical Society, Burlington House, W., 8 p.m.
Sir Ernest Rutherford, "Artificial Disintegration of Elements."
Mechanical Engineers, Institution of (Midland branch), The University, Birmingham, 7 p.m. Mr. W. R. Parsonage, "Aircraft Tubes."

FRIDAY, FEBRUARY 10. London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 4.30 p.m. Sir Joseph Broadbank, "Progress in the Port of London."
Fine Art Trade Guild, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7 p.m. Lecture by Mr. G. P. Gaskell.
Royal Institution, Albemarle Street, W., 9 p.m. Prof. W. D. Halliburton, "The Teeth of the Nation."
Electrical Engineers, Institution of (Irish Centre), at the Royal College of Science, Dublin, 8 p.m. Mr. R. D. Archibald, "A Method of Regulating the Voltages on two Sides of a Three Wire C. C. System, Equalised by Static Balancers."
Malacological Society, at the Linnean Society, Burlington House, W., 8 p.m.
Physical Society, at the Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, FEBRUARY 11. Royal Institution, Albemarle Street, W., 3 p.m. Prof. E. de Selincourt, "Humorists of the Seventeenth Century." (Lecture II.)
Teachers in Technical Institutes, Association of, Technical School, Bolton, Lancashire, 2.30 p.m. Mr. A. E. G. Brookes, "Design, Colour and Structure of Textile Fabrics."

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday of the week preceding the Meeting.

*For Meetings of the ROYAL SOCIETY OF ARTS, see page 205.

Journal of the Royal Society of Arts.

No. 3.612.

VOL. LXX.

FRIDAY, FEBRUARY 10, 1922.

All communications for the Society should be addressed to the Secretary, John Street Adelphi, W.C. 2.

NOTICES.

NEXT WEEK.

WEDNESDAY, FEBRUARY 15th, at 8 p.m.
(Ordinary Meeting.) CLOUDESLEY BRERETON, M.A., Divisional Inspector to the London County Council (Modern Languages), "The Necessity of Speech Training, and the Need of a National Conservatoire." SIR HENRY NEWBOLT, C.H., D.Litt., LL.D., Chairman of the Departmental Committee on the Teaching of English, in the chair.

CANTOR LECTURE.

On Monday evening, February 6th, Mr. C. Ainsworth Mitchell, M.A., F.I.C., delivered the third and final lecture of his course on "Inks."

On the motion of Mr. C. T. Courtney Lewis, a vote of thanks was accorded to Mr. Mitchell for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

TENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 1st, 1922: SIR CECIL HARCOURT SMITH, C.V.O., LL.D., Director and Secretary, Victoria and Albert Museum, in the chair.

The following candidates were proposed for election as Fellows of the Society:-

Forrest, L. R. W., London.
Gomat, C. S. Ganapathier, Madras, India.
Soames, Mrs. Geraldine, Rugby

The following candidates were balloted for and duly elected Fellows of the Society:-

Ainsworth, E., London.
Anderson, Roy King, Bassein, Lower Burma.
Ashworth, Sidney Herbert, A.I.Mech.E., V.D.
Naihati, Bengal, India.
Bando, S. N., B.Sc., Calcutta, India.
Brooks, Milton, Calcutta, India.
Chak, Pandit Sangam Lal, Lucknow, India.

Choudhari, Dhanji Garbad, London
Desai, Kapaldas Viharidas, Gujerat, India.
Douglas, Frederick William, B.A.Sc., A.M.E.I.C.,
New York City, U.S.A.
Hall, Willred, B.Sc., Tynemouth
Murphy, Walter P., Chicago, U.S.A.
Nelson, Frank, Bombay, India.
Nichols, Ronald Herbert, Kulti, Bengal, India.
Oughton, Ernest, O.B.E., M.Inst.M.M.,
Hindubagh, Baluchistan, India.
Piggott, Leonard Charles, F.R.G.S., Buxton,
Nr. Norwich.
Pratley, Philip Louis, M.Inst.C.E., Quebec,
Canada.
Sherman, Major Norman Clarence, Esquimalt,
B.C., Canada
Soundy, L. H., London
Tait, Louis Benjamin, Rangoon, Burma
Taylor, S. H., Cawnpore, India.
Thaker, Narmadashanker Ganpatram,
Ahmedabad, India
Vernon, George Shirra Gibb, Calcutta, India.
Walker, Herbert Wilson, Seascale, Cumberland.
Warburton, Walter Granville, O.B.E., J.P.,
Bombay, India.
Wicksteed, Henry K., B.A.Sc., M.E.I.C.,
Toronto, Canada
Yabsley, Percy, Aylesford, Kent

A paper on "Surface Printing by Rollers in the Cotton Industry; a comparison with other Processes of Printing Patterns for Cretonne, Dress Material, Wallpaper, etc.," was read by MR ARTHUR WILCOCK.

The paper and discussion will be published in the *Journal* of February 24th.

DOMINIONS AND COLONIES SECTION.

TUESDAY, FEBRUARY 7th, 1922; LORD CLINTON, Forestry Commissioner, in the chair.

A paper on "The Timbers of British Columbia" was read by MR. WILLIAM TURNBULL, Timber Commissioner for the Government of British Columbia.

The paper and discussion will be printed in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

NINTH ORDINARY MEETING.

WEDNESDAY, JANUARY 25TH, 1922.

MR. ALAN A. CAMPBELL SWINTON, F.R.S.,
Chairman of the Council, in the Chair.

THE CHAIRMAN, in introducing Mr. Howard Edmunds, the author of the paper to be read that evening, said he wished to draw attention to the fact that an original invention was about to be described by its inventor. It was always a great privilege to hear such things described by the actual inventor, and in the present case the process which was the subject of the paper was entirely the invention of Mr. Howard Edmunds.

The paper read was :

PHOTO-SCULPTURE.

By HOWARD M. EDMUNDS.

Photo-sculpture is a process by which, through the agency of photography, we are able to produce carved replicas in relief, or in the round, of any solid object.

The carrying out of this process has been helped very much by recent advances in plates, and by the highly accurate photographic lenses now available. The subject is so much in its infancy that criticism of the results obtained should be tempered by reflection on the difficulties of any new development of this kind. The basic theory may be correct ; but in carrying it out much has to be learned by experience.

The broad principle upon which the method to be described this evening depends, is as follows. By projecting a system of markings successively upon a plane surface and upon an irregular solid, one can register photographically the change in form which the markings undergo due to the substitution of the solid for the plane surface.

To make this clear we must first consider the case of photographing an image upon a plane surface. This is what occurs when a picture or print or map is photographed. In general such pictures are photographed by a camera with its lens facing the middle of the picture, and the plate parallel to the plane of the picture. When this is done, if a well-corrected lens is employed, a facsimile of the form of the picture is obtained, differing only in scale from the original. This also happens if the lens of the camera does not face the middle of the picture, provided the axis of the lens is still at right

PORTRAIT BAS RELIEF FROM LIFE CARVED IN

PROCESS.

WORK UNTOUCHED AFTER LEAVING CARVING
MACHINE

angles to the plane of the picture. This fact is made use of in Photo-sculpture. I would also like to make it clear at this point that the camera and plate may be turned at an angle to the picture, when a foreshortened result will be obtained ; and, for example, the sides of a rectangular picture will appear to converge. This second photograph may be converted to the undistorted form by enlarging it with the easel inclined suitably, so as to correct the distortion of the original negative. This point, also, is made use of in the process of Photo-sculpture.

A number of types of markings are suitable for carrying out this process ; but in the description which follows I will keep to the one which has been used in the experiments up to the present ; that is, a spiral line of the same form as the groove in a gramophone record. I also propose to use a grid, of parallel straight lines.

We must now consider what the effect will be of replacing a plane surface by a solid object. First it is clear that, viewed from any position (except that of the projector lens) the lines on the solid object will be displaced from the position they occupied on the plane surface. In order that these displacements may follow a definite law which can be taken advantage of in a carving machine, the camera must be placed with its lens in the nodal plane of the projector lens. When this is done, all points on the lines of the undistorted figure move in parallel lines.

I do not want to labour the mathematical proof of this, as it is somewhat technical ; but it is borne out by the faithfulness of the result to the form of the original solid object.

Having secured a photograph in which the lines are clearly visible as focussed upon the face of the sitter, the next step is to prepare what I have called a guide plate, to be used in the carving machine. If the camera is placed with its lens axis parallel to the projector lens axis, and the plate of course normal to this axis, then the negative will be in the correct form for use as a guide-plate. It is often convenient to place the camera with its lens pointing straight at the object, so as to use the axial zone of the lens, which is apt to be better corrected than the marginal one. When this is done, the resulting photographs must be enlarged, and corrected in such a way that a photograph taken of the spiral projected on a plane surface is undistorted, and of exactly the right size. This is the method I have adopted up to now in making the carvings that are shown here to-night. The enlargement is made on opal glass, so that there shall be no change in dimension owing to the process of development, as would be the case if bromide paper were employed.

Having secured a guide-plate, the next step is to use this in a suitable machine for producing the carving. It is important to bear in mind that the guide-plate consists of a plane surface, with a series of lines clearly shown upon it. These lines are not a true spiral ; but their displacements from the true spiral form are all parallel, and of an amount proportional to the depth of the object at each particular point. The straight line shown on the guide-plates indicates the direction of displacement. The guide-plate is fixed to an iron carrier in the machine ; and this has a compound movement imparted to it, giving it a spiral movement ; but, at the same time, any line moves in a path so that it is always parallel to its former position. In other words every point on the plate describes the same spiral. The model I have here will make this clear.

A drill and a microscope are mounted on a steel rod, free to move in the direction of its length, but constrained from any other movement. The guide-plate is fixed to the plate carrier, so that the direction of the displacement line is parallel to the microscope movement. A headstock is fixed with its

axis parallel to the microscope and drill movement, and is given both rotation and side travel, so that the drill carves out a spiral form on the material to be carved, which is fixed to the headstock. It only remains to follow the lines on the guide-plate with the cross-hairs of the microscope, and the rapidly rotating drill carves out furrows of varying depth in the carving block, thus producing the relief carvings.

The relative distances of camera and projector to the projector and the object photographed determines the degree of relief. In practice I have found from one fifth to one-quarter the most suitable ; but that will doubtless be modified by further experience.

Work has been done in ivory, alabaster, and wood ; and the number of lines per inch has been 20, 40 and 100. The fineness of modelling obtained by carving 100 lines per inch is such that the grooves in the carving are scarcely noticeable ; just as in a half-tone reproduction, the lines of the screen are not noticed, and the reproduction appears like any ordinary photograph, although in reality it is a series of dots of varying size and form.

The amount of labour necessary to complete one of these carvings can be judged by the time taken. One with about 200 lines requires about eight hours. The work is very interesting, as the results can be inspected between the cuts, and the progress noted. Close attention is necessary to avoid a false cut ; and hours of patient work may be spoiled by a single mistake ; but with practice the chance of this is almost entirely eliminated.

I have some diffidence in touching upon the probable scope of this invention ; but making portraits in relief would seem to be a promising field. The great accuracy of which the process is susceptible will render it possible to reproduce existing works of sculpture on any scale and in any degree of relief ; and no doubt this could be made use of for decorative purposes. Just as photography has made possible the enjoyment of the great paintings of the world to a much greater number of people, so it is perhaps not impossible that the camera may do useful service in reproducing the form of the great masterpieces of sculpture.

(The paper was illustrated by lantern slides and a cinematograph film).

DISCUSSION.

THE CHAIRMAN (Mr. Alan A. Campbell Swinton F.R.S.), in opening the discussion, said he was sure the author had made very plain to the audience the manner in which the invention worked. Personally he had had the opportunity of visiting the author's home near Brighton and had seen the actual machinery in operation. The machinery was very heavy and therefore it was not possible to bring it to the meeting that evening, but in a way the cinematograph made the process clearer than it would be to anyone seeing the actual machine at work, because the cinematograph enlarged it on the screen. As far as he knew, the invention was an entirely new one; he did not think anything of the kind had ever been suggested before. The method of registering variations in depth by deviations from either a straight line or a spiral was a most ingenious device. It seemed to him that there must be many applications for the process; tombstones seemed the natural thing to think of first, but he supposed it could be adapted also to the making of such things as medals. He took it that the machine could be reversed so as to make a concave engraving instead of a convex one, and by that means it would be possible to make dies for the pressing of medals. Then of course the invention provided a wonderful method of reproducing sculpture, and that could be done on any scale. The scale could be varied either in the photographic part of the process or by merely altering the gear wheels in the reproducer. The invention seemed to him to have endless possibilities. He was not an artist but looked at such things entirely from the scientific point of view, and he had been recently taken to task by an eminent Academician who said that such things were quite wrong—that they were not art. His reply had been that no one claimed that they were art. If it was agreed that there must be no reproductions of people except through the medium of the artist, ordinary photography would also have to be abandoned, but there was no doubt that photography had come to stay and had very useful functions, and he felt that the author's latest development of photography had also great possibilities and many uses.

SIR FREDERIC KENYON, K.C.B., D.Litt., LL.D., F.B.A., (Director and Principal Librarian, British Museum) said he was neither a sculptor nor an artist, and the application of the author's invention which interested him most was one to which the Chairman had just referred, namely, the making of replicas of ancient sculpture and especially replicas of a smaller size. Reproductions of ancient sculpture could of course be obtained by means of casts, but it seemed to him that there might be a use for reduced size replicas, which one could be certain were not done merely by the eye but were mechanically accurate and preserved the original proportions.

He would like to know whether the author had tried that application of the process, because in that way replicas might be obtained which would be useful in art schools and would also be valuable as ornaments in private houses where there was not sufficient room for full size reproductions. As a rule one mistrusted the small reproductions of statuary or reliefs that were seen in shops, because their accuracy could not be relied upon. If he understood the author's invention aright, it would give a perfectly accurate reproduction of the original, and he could see no objection to a process of that kind. If it was used in the case of a living person it might not be as good as the work of a great artist, because it would only bear the same relation to a great artist's bust or bas-relief as a good photograph bore to the work of a great painter, but in reproducing a work of art such as an ancient bas-relief all that was required was accuracy and fidelity, which he thought the author's invention would give. He would like to know whether the process was applicable to marble, or whether marble would be too hard for the purpose. If it was applicable to that substance, reproductions could be obtained of the frieze of the Parthenon, on any scale desired and in the original material, which would give what plaster casts could not give, namely, the qualities of the surface. If that was possible, it seemed to him that at any rate in that direction there would be very valuable applications for the author's invention.

MR CECIL THOMAS said the invention was a most interesting and remarkable one and the author was to be congratulated on devising such a very ingenious machine, but it was the use of that machine with which he, in common with his brother artists, was more concerned. Did it make for progress or the reverse? He was sorry to say that in his opinion it made for the reverse, because he could not see that any advantage was to be gained by producing portraits, or, as a matter of fact, any work of art, mechanically from life. The quality that the touch of the artist gave was bound to be lost. If he might criticise the illustrations the author had shown, he would take one detail, the ear. In none of the reliefs shown had the ear the emphasis of life. The ear was an extremely difficult thing to model, and mechanically it was of course still more difficult to reproduce. Even in the Janvier machine which reproduced artists' models the details were sometimes lost, and that machine worked about 300 lines to the inch. The point about an automatic or mechanical work of art was that there could not be any quality or touch that emphasised character and that made a real work of art what it was—there could not be any expression in it. As the author said, it took eight hours to produce a relief portrait by his machine and as any competent artist could do that same portrait in from one to three hours, he failed to see what

was the advantage of the author's invention, apart from the advantage to the sitter. It was very unpleasant for a man to have to sit for three hours and it would be most delightful for him to be able to go to the nearest photographer and sit for two seconds while he was photographed for a relief portrait. So far as the result was concerned, the average member of the public was not particularly interested in the quality of the work. It was a remarkable fact that, when an artist produced a portrait with which he was dissatisfied and which he felt was not at all his best work, the average person would say it was charming—so long as it had some resemblance to the original, people were quite satisfied. But it was the quality of the work which all the movements associated with art were concerned to foster. The Arts and Crafts Society, the Art Workers' Guild and all such Societies tried to lift the arts and make them a more emphatic means of expression of the artist's mind. Mechanical devices, unless they were the servant of the artist, could not make for progress; they could only make a step backwards. Scientifically it was progress; artistically it was the reverse. The Chairman had referred to photography as being an art, but it was only an art when it was in the hands of an artist, and very few artists cared to give their time to mechanical means of reproducing what was in front of them when they had the ability to do it with their hands and to express their minds. He was afraid he had not been very optimistic in what he had said, but he viewed mechanical means of reproduction that took away the artist's control as a step in the wrong direction.

MR. ALLAN G. WYON said he wished to support what Mr. Cecil Thomas had just said. Whilst he greatly admired the author's invention as a piece of machinery and as a very remarkable achievement of its kind, it could not in the nature of the case give that which only the artist could give. It might be said that it did not pretend to do so, but it was important that the artist should emphasise that point. The photograph at its best could not give what the portrait painter could give. The difference between the work of an artist and the work of a machine was that the artist exercised a power of selection: he chose certain things to emphasise and certain things to make insignificant. For instance, the ear had been referred to by Mr. Cecil Thomas, and a sculptor in modelling a face in relief from the side view often made the ear inconspicuous, lest it should take to itself too much emphasis and importance. He mentioned that as a single instance, but that system of selection was what constituted a work of art. From every other point of view he had a great admiration for the author's machine and for the work he had shown that evening.

MR. H. LYON THOMSON said he had been deeply interested in the paper, the process described therein being, as the Chairman had pointed out, an entirely fresh departure from anything of the kind that had been previously attempted. Early in the sixties there was a process—or what purported to be a process—of photo-sculpture in the round, in which a building was erected with 24 cameras placed at equal distances and photographs were taken from each point of view, the photographs being then projected on a screen and, by means of a pentagraph, reduced. It was afterwards ascertained, however, that a skilful artist was employed on the work, only the apparatus being shown to the public. He thought the author's invention led one into an entirely new train of thought, and it was difficult to see the ultimate results that might be achieved by a continued application of the system. He would like to ask the author whether he had made any attempt to produce the spiral in relief by means of any gelatine process, so that the machine would automatically follow the lines without the intervention of the human hand. With regard to Sir Frederick Kenyon's remarks about reproducing classical works of art on a small scale, that did not present any difficulty at the present time, because the ordinary reducing machine would do that from a mechanical point of view with perfect accuracy. Such machines as were employed on medals would also of course, either from a cast or from a counter-cast, engrave on steel, by means of the diamond point, a die either in reverse or in relief.

MR. J. TAYLER FOOT said he had done a considerable amount of work with the ordinary reproducing machine and had made the models necessary for that machine in wax and plaster. He was much interested in the author's invention, and thought that the method it provided of making a rough model for a portrait medal would be of great help to him at the present time. He could then finish it by hand and thus make it into a work of art.

In reply to questions by COLONEL C. M. SIMPSON, D.S.O., R.F.A., MR. EDMUNDS said that an electric motor was used to work the machine. It did not work at a constant rate, there being a speed variation which provided for two speeds being used.

MR. G. ELLIOT ANSTRUTHER said that, speaking as a man who was neither an artist nor a scientist, he thought those present that evening had been witnessing the exposition, by the inventor himself, of a remarkable achievement of ingenuity for which he claimed no more than he had been able to prove. The author had demonstrated that, by the application of certain mechanical principles in a new and original

way, he had secured the translation of something on a plane surface into something on a convex surface, and that, as an invention in a state of infancy, his machine had attained an obviously remarkably high degree of fidelity. Without wishing to cast any aspersions upon any of the remarks made by previous speakers, he personally felt that, in suggesting a kind of comparison between what was to be expected from the artist and what was to be expected from the mechanician, it must be borne in mind that the author had not put forward his invention otherwise than as a mechanical device. There was a danger, in dealing with fidelity, of imagining that there was a certain infallibility about the portrait painter and that he was going to exhibit a higher degree of fidelity to the original than the author's machine would do. It ought not to be assumed that because the means of production were a man's hand, brushes and palette the result would necessarily be a more faithful representation of the original than would be produced by a photographic process or by the invention which the author had described. He thought everyone present had been intensely interested in the lucid and modest exposition the author had given of an invention which, as the Chairman had said, was one of very remarkable ingenuity and an unknown quantity in regard to future developments. He was sure that, in saying he had greatly enjoyed that exposition, he was expressing the feelings of everyone present.

THE CHAIRMAN (Mr. Alan A. Campbell Swinton, F.R.S.) said he had been very interested in the remarks made by Sir Frederick Kenyon. The author had brought to the meeting some actual reproductions of classical statuary on a small scale which he thought showed quite clearly that the process was adapted to the reproduction of works of art. With reference to the question of art he might mention an incident that had occurred a few days ago. A member of the Council of the Society, Sir Charles Parsons, had had his portrait painted by Sir William Orpen and it was desired to have that portrait reproduced. He asked Sir William Orpen whether it would be best to have a mezzotint made of it, but Sir William's advice was to have a photogravure made. Photogravure was a purely mechanical process, but Sir William Orpen recommended that in preference to making a mezzotint, which was not a purely mechanical process. It would therefore be seen that there was some difference of opinion in the artistic world on the subject of mechanical processes.

MR. HOWARD B. EDMUNDS, in replying to the discussion, said the Chairman had already answered Sir Frederick Kenyon's question about reproducing classical works of art by means of photo sculpture. One advantage that that process possessed was that it could

reproduce a work of art in a different degree of relief. The Janvier machine had been referred to by Mr. Cecil Thomas. That was a very delicate and beautiful machine for reproducing the works of an artist on a smaller scale but in the same degree of relief. In touching on the artistic side he was absolutely out of his depth, and he gave place to the two gentlemen who had criticised his invention from that point of view, but he did not claim for it anything more than that it could reproduce the form of the original object. Mr. Cecil Thomas had said that photography became an art in the hands of an artist, and it was not impossible that the same might apply to his invention in the future and that it might produce results which would not be unpleasing to the artist.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Edmunds for his interesting paper and demonstration, and the meeting then terminated.

MR. HENRY EDMUNDS, M.Inst.C.E., M.I.E.E., writes:—

Though present at the Royal Society of Arts when my son read his paper on Photo-Sculpture, I did not take part in the discussion; but I should now like to add my views. Faraday at the Royal Institution in the last century demonstrated his classic discovery that an electric spark could be produced at the ends of an insulated wire surrounding a permanent magnet when the armature or keeper was detached from the magnet. He was asked what was the use of it? He replied 'What is the use of a baby.' That discovery was the forerunner of our present systems of electric generation by dynamo-electric machinery, and the transmission of energy for lighting, heating, and power. In 1877 I was present at Edison's workshop in Menlo Park (New Jersey), and witnessed the first recording and reproduction of human speech by the means of a simple diaphragm equipped with a drawing pin for a stylus, and a sheet of tinfoil mounted on a grooved brass cylinder turned by hand. This was indeed an epoch-making event! It was considered wonderful at the time; but of no commercial value. It was over ten years before Bell, Tainter, Berliner, and Edison—all pioneers—could produce a machine that could talk—and earn dividends. In 1888 I read a paper before this Society on talking machines, which were then still in their infancy. I may appropriately ask 'What is the value of those infants to-day?'

There are modern Herods who do not hesitate to seek the young child's life: to strangle it in its infancy: lest it should grow up and become a menace to existing interests. There is a parallel between Phonographs and Photo-Sculpture. The one records and reproduces sound: the other records and reproduces form.

It has been absolutely proved, beyond doubt, that the recording of "form" is a complete success, optically and photographically; and the interpretation of the record by mechanical means is also most encouraging. Instead of ten years elapsing, as with the Phonograph, before a satisfactory reproduction of sound was effected, in less than ten months we have succeeded by means of Photo-Sculpture in giving faithful examples of the reproduction of "form" in various media—wood, stone, ivory, and metal. The development and improvement in each successive instance has been most marked; and demonstrates that only experience is necessary to arrive at complete results.

In reply to the questions as to what artistic use, and what commercial value, there may be in this invention, I would say, from my own observation, to the sculptor, that he can have an exact record of the form of his subject produced photographically in ten seconds, without any inconvenience to the sitter, who may be a busy man and unable to spare time for a careful modelling in clay, and later retouching to perfect the likeness. It is true that one may get a "sculpturesque" impression—as in nature we meet with profile rocks giving at a certain angle a vivid suggestion of some notability, varying according to the imagination of the observer; but such tours de force are seldom satisfactory, even at the hands of an artistic genius. With this present process it is no longer necessary to prepare a mask in plaster—objectionable to the living; and a caricature of the dead. The photographic record can give the living smile or frown, or any other characteristic expression of the subject; and thus give the impression of actual life. The finished work can be upon any required scale, magnified or reduced, and yet preserve the exact proportions of the original; and it is not in soft wax, or clay, but in imperishable marble, and eternal bronze.

Knowing that all these things can be done, the commercial success of the invention is assured. Such success will come slowly or quickly, according to the financial support it receives—for all new processes need nourishment in infancy.

It has been objected that Photo-Sculpture is not creative: that it cannot rival the artist, who may by his skill and genius evolve a form of charm and beauty according to his own ideal, but the function of Photo-Sculpture is to reproduce copies of these ideals, preserving every touch and detail of the original, on any scale, large or small—a feat which can seldom or never be obtained by an ordinary workman, however painstaking and clever he may be. An additional application is the presentation of life-like portraits of the individual, which can be executed at any time after the "record" has been obtained. Furthermore, Photo-Sculpture may be used to multiply works of beauty, classic or modern, giving a wider field for the

talent of the artist, educating the artistic sensibility of the public; and increasing the human enjoyment of the Fine Arts. In the art of architecture there is an unlimited field that has not yet been touched. Photo Sculpture is thus the handmaid, not the rival of the sculptor. They both will live and inspire one another.

The Chairman referred to grave-stones, as among the possible uses of the system. When I was last in Genoa, and visited the famous and beautiful Campo Santo, I saw hundreds of memorials in marble which had merely had ordinary photographs let into the stone, and, although protected by glass, many of these were faded and useless. Had Photo Sculpture been invented before the Great war, fifty per cent of the war portraits would have been taken by this process, and thus friends and relatives would have had them as 'records' for future memorial. In France and Belgium to-day, we and generations to come might have visualised the heroes who gave their lives for King and Country, instead of an undistinctive name, or a number.

When the paper was read, the cinematograph pictures did much to illustrate the system, and help the audience to understand the process, which might have been more difficult to grasp from only the spoken word of the lecturer. Briefly, one may describe it as follows—In a dark room light from a magic-lantern is projected on to the face of the subject, through a screen of glass upon which is a series of lines in a spiral form—something like a gramophone record. These lines, falling on a plane surface, would show as a uniform spiral: but when projected on to the human face, for example they become irregular and distorted. A photographic camera at the same time receives on its sensitive plate, the object before it, with all its distorted lines. This plate is fixed and developed, thus furnishing the "record" which is afterwards employed in the carving machine, enabling the operator, by carefully following these lines, to control a revolving cutter, or drill, which effects a cut of varying depth in the material upon which it is acting; and thus produces a solid copy in the three dimensions—length, breadth, and height—of the subject upon which the lantern has thrown its rays.

NOTES ON BOOKS.

CANE SUGAR Revised Edition By No¹ Deerr London: Norman Rodger 1921. 42s. net.

We have here a practical text book adapted to the needs of the planter or planter-manufacturer, and one which deals with operations and conditions incidental to cane sugar plantations, as also to works associated with the plantations. In other words, the present volume fully and satisfactorily covers minute details from the preparation of the soil to the

output of plantation white sugar, and such incidentals as rum and molasses.

Mr. Noel Deerr's book embodies 644 + VIII. large octavo pages, 29 inset plates of which many are admirably executed in colours, so as to illustrate insect pests (plate XVI. opposite p. 144) or the tints and characteristics of the standard varieties of cane. (Plates I to X.) Besides the plates, there are 356 engravings in the text.

That the author is an enthusiast, and that every detail relating to his subject is a source of delight to him is obvious almost at the first, and the work has all the merits that enthusiasm and painstaking can impart—clear, concise and unmistakable wording, full references to other books and authorities, good indices and that practical stamp which comes of a career devoted to this subject.

The sugar cane region is carefully traced, in reference to the varieties and their economic value or characteristics; the range in habitat of this remarkable giant perennial grass, which covers the warmer regions all round the earth, where abundant water supply is available, although botanists consider Eastern Asia to be its original home. As an extreme it may be mentioned that at the Great Exhibition of 1861, there was an exhibit of sugar from canes grown in Surrey. In size the varieties show wide range, from the small reed like canes grown by the Ryots of British India to the elephant cane of Coochin China.

As a part of his study of the vital functions of the cane in special relation to pests, climate and surroundings Mr. Deerr shows (p. 5) a highly instructive section of the leaf in condition almost as living; the sudden fixing or killing of the tissues with osmic acid vapour while the leaf was on the plant, having secured a condition perhaps unobtainable by other means. The leaf is the essentially vital organ of the plant, and the 37 marked regions are, together with the text, remarkably instructive as to the vital functions, life history and the attacks of disease. Practical botanists will study this section with interest.

Natural and artificial fertilization is considered at great length, and also the questions incidental to inheritance in seedlings. In Hawaii the seeds are sown in boxes, the mould being a rich vegetable product obtained from the neighbouring forest. This mould is sterilised by boiling to kill seeds of other grasses. In India the method is somewhat different, but in all cases, great care appears to be required at this stage, and when about two months old, the seedlings are ready for transplanting to flower pots or wicker baskets, but it is after planting out in the open field that the process of selection begins.

It thus becomes apparent that the culture of the cane, like the extraction of the sugar, is a highly delicate matter, but we have not even

touched on many of the difficulties and delicacies of culture, as detailed by the author.

The extraction and refining are treated of in the same thorough way by Mr. Deerr, and the latest and best evaporating and centrifuging devices are fully described and figured; mainly from the point of view of restraining inversion of the crystallisable sugar and minimising partial wastage in the direction of molasses or rum. In respect of the latter product, the relation of ferments and conditions of fermentation to flavour are thoroughly considered.

The testing and analysis of sugar and sugar products are by no means neglected, and until we had glanced over the chart of optical systems in use for polarimeters (p. 483) we did not realise that they are so numerous.

The author is evidently a scholar and a student of economics, in addition to his technical qualifications, and he shows us what a technical book should be, whether as regards indexing, classification of patents, bibliographies or references, and we feel a satisfaction in receiving a book like the present volume from one of our Indian fellow-members of the British Federation; a book which should certainly be in the hands of every sugar manufacturer or merchant. It may also give lessons in system and method to all manufacturers, and, further, it should prove a delightful library book for the general reader. As an example of general interest reference may be made to Plate XXVII. and the accompanying text; these elucidating the methods adopted in Cuba for cooling water on an extensive scale.

THE HANDICRAFT ART OF WEAVING. By Thomas Woodhouse. Oxford Technical Manuals. London. Henry Frowde, and Hodder & Stoughton. 6s.

TEXTILE MATHEMATICS. Part I. By Thomas Woodhouse & Alexander Brand. London, Glasgow and Bombay: Blackie & Son, Ltd. 3s. 6d.

The first named book consists of 143 pages illustrated by 125 process blocks, the majority of which are of good scale, well lettered and fully explained. Others, of primitive or native weavers at work, are not so clear; indeed, some of native weavings are almost unintelligible and very small in size. Mr. Woodhouse's account of the art of weaving runs into 142 pages, and is based upon an interesting analysis of such methods as are practised by natives of the Upper Congo, by Mexicans and by Armenians, thus suggesting the large area involved in the art of weaving by hand. Modern power-driven machinery to produce textiles owes its evolution to such handicraft methods. To convert the technical instruction set forth in this book into real knowledge, supplemental practical training with appliances, etc., is

obviously necessary. The last twenty pages relate mainly to different sorts of carpet weaving and as regards the hand work, students of the subjects will find useful additional information in a small ninepenny publication at the Victoria and Albert Museum—"Notes on Carpet Knotting and Weaving," by Mr. C. E. Tattersall.

Mr. Woodhouse's title to Chapter VII, "Gobelin, Ardehil and Oriental Fabrics," is rather too roving, and the chapter itself supplies but a scrappy exposition. Are not taste in the composition of patterns, and the study of standard examples, points which might have been suitably mentioned, especially in connection, for instance, with Italian 15th Century fabrics, later French, and surely Chinese, Indian and Japanese ones?

The second of the above mentioned books embodies, as stated in its Preface, an explanation of the general principles involved in all preliminary books on mathematics. The exercises at the end will undoubtedly help students to work out simple applications of these general principles to the calculation of dimensions of textiles and of machinery for their production.

PETROLEUM. By Sir Boverton Redwood, with a foreword by Sir Frederick W. Black. Fourth edition. Three volumes. London: Charles Griffin and Company, Ltd. 1922. £5 5s.

Redwood on petroleum has long been regarded as the exemplar or pattern book of reference with respect to all matters relating to petroleum in its varied aspects, from natural gas to bitumen: it being impossible to find a logical or consistent halting place between these extremes. Notwithstanding the fact that the greater part of the new matter for the present edition was written under the stress of war times, and that the many alterations and additions involved re-setting the whole of the type, the author, who was helped by many willing friends, has given the public a new edition which adds, if possible, to the old reputation.

It is sad, however, to have to record that Sir Boverton did not live to finish his work, but his friends and helpers have completed the task.

In the new edition of Redwood's Petroleum, we have a remarkably good illustration of those features of book construction which experience has shown to be convenient for the book user. The paging runs sequentially from 1 to 1353 through the three volumes, and the range of pages contained in each volume is indicated on the back; thus is avoided all worry in entering two data, page and volume. Similarly, the index is unified so that one can never find oneself searching in the subject index for a name or *vice versa*. Moreover, when there is but one index, there cannot be the annoyance of finding that several of the unusual compound names

have drifted over to the subject matter index. The unified index, 34 pages of small but remarkably clear printing, not only gives reference to the pages of Sir Boverton's volumes, but also to the works in the Bibliography which may be consulted with advantage: the page numbers and the Bibliography numbers being kept apart in an ingenious and satisfactory manner. The Bibliography itself is a remarkable feature, 162 pages and 8804 items all numbered so as to be readily indicated in the general index as mentioned above. The maps, with petroleum areas marked in red, form an atlas of the world as far as petroleum is concerned, and in other respects they are good up-to-date maps.

Redwood on Petroleum in its 1892 form is an impossible work to review satisfactorily in the usual fashion: all the expedients and wiles of the reviewer's craft failing in this exceptional instance. There is an old canon that for a review to be adulatory in the fullest sense there must be mention of some trivial fault, just to show how strictly impartial the reviewer is. Even in this we are baffled, as we have not been able to find the trivial fault.

It appears to us that the best possible review of an exceptional work like that before us, would be a *brochure* of about 16 pages, so selected as to indicate the leading characteristics. Any page of the bibliography or of the index would be an exemplar, the whole being balanced and in ratio. For instance, p. 1331 (index) will indicate the inclusion of such widely various subjects as "Hexadecane: Specific Heat of"; "Hong Kong: Dangerous Goods Ordinances"; "Hawking Petroleum"; "Hinks's Duplex Burner"; "Heckmann Naphtha Still"; and "Heel-ball."

A selected half dozen pages would exemplify the thoroughness in technique, ranging from minute detail, as the study of laboratory fractionating columns (p. 747), and the rivet catcher on the rod of the oil well pump (p. 421), to such large scale appliances as the vacuum still (p. 507) and the four other typical stills figured on the next preceding page. Other selected pages might illustrate the thoroughness of the work with respect to spray burners for light, furnace work, and power by liquid fuel. A page from the section on petroleum in Great Britain (pp. 38 to 13) should serve to illustrate the completeness of the historical summaries: this one ranging from the year 1667 to the recent Government Grant for Systematic investigations and the finding of oil in the experimental boring at Hardstoft in 1919, followed by the report (September, 1920) as to the great gas blow in one of the Scottish borings.

OBITUARY.

SIR FRANCIS HENRY BARKER.—Sir Francis H. Barker, who was elected a Fellow of the Society in 1920, died at Cannes on January 28th.

He was born in 1865, and educated at Clifton College. He travelled extensively in Europe and Asia Minor, and was especially interested in Russia, being President of the British-Russia Club, and Chairman of the Executive Council of the Russo-British Chamber of Commerce. He was a director of Vickers, Limited, and of several other important companies. A knighthood was conferred on him in 1917.

TRADE OF THE BELGIAN CONGO.

The Belgian Congo covers an area of about 910,000 square miles, comprising rich agricultural lands and mining districts. For the purpose of government, the Congo was in 1915 divided into four Provinces—Kongo Kasai, Equateur, Orientale, and Katanga, which are in turn sub-divided into districts. The metric system of weights and measures is used, and by decree of December 28th, 1919, the Belgian franc was made the only legal money tender.

Of the three seaports of the Congo—Matadi, Boma, and Banana—Matadi is the only one of importance. Steamers up to 8,000 tons can be docked there. From this point there is railway connection inland to Leopoldville. There are six different ways to enter the Congo, including the Matadi route. They are as follows: Via Matadi (93 miles from the mouth of the Congo), via Cape Town (South Africa), via Dar-es-Salaam (formerly German East Africa), via Beira (Portuguese East Africa), via Mombasa (British East Africa), and via the Nile.

For interior commerce and travel there were, on December 31st, 1917, 1,264 miles of railways in the Congo.

Another important route for commerce is the Congo River, which, with its branches, furnishes over 9,000 miles of navigable waterways, and presents only three impassable barriers to river steamers, the first on the lower Congo, from Matadi to Leopoldville, and the other two on the upper Congo, from Stanleyville, to Ponthierville and from Kindu to Kongolo. The navigable portions of the Congo River are connected by rail with each other.

The commercial development of the Congo, writes the Secretary to the United States Trade Commissioner at Brussels, has gone forward rapidly from the time it has been opened up to the world trade, and its development since 1900 has been particularly encouraging. The mining industries have been showing increasing returns yearly, and very successful experiments have been reported in agriculture. Coffee, cotton, and rice have already passed through the experimental stage, and are being exported in considerable quantities. Rubber has been a standard export of the Congo, but the first cultivated plantations in the

colony came of age to be profitably worked only in 1914. These new plantations should add greatly to the commercial value of Congo rubber exports, as the rubber trade gives preference to cultivated rubber over the wild products. Other products exported from the Congo in quantity are palm nuts, cocoa, copal, copper, diamonds, gold, ivory, palm oil, and wood.

The effect of the war on the Congo is reflected in the greatly increased exports since 1913, due to the urgent European need for raw materials and supplies of all sorts. The following figures show the volume of certain exports from the Congo, in the years 1913-17:—

	1913	1914	1915	1916	1917
	Tons.	Tons.	Tons.	Tons.	Tons.
Rubber	3,567	2,213	2,144	2,969	3,700
Palm nuts	7,092	7,925	10,852	22,038	38,487
Cocoa	899	575	610	758	771
Ivory	272	292	211	346	267

The exports of copal, after having increased considerably in 1914, were greatly diminished during the war. The industry is again recovering, the export figures for 1917 being 7,329 tons. The exports of palm oil have shown an exceedingly rapid increase from 1,957 tons in 1912 to 5,309 tons in 1917. The exports of palm nuts, however, have increased even more rapidly, as will be seen from the foregoing table.

The export of coffee, which has only recently been attempted, has met with success. An attempt to export coffee in 1915 resulted in the sending of 29 tons abroad. In 1917, 167 tons were exported.

Many experiments have been conducted in rice culture, and the industry has met with considerable success on the upper Congo in the Province of Orientale. In 1917 there were 693 tons exported.

Experiments in cotton culture have met with very good success, the production in 1920 being estimated at 4,000 bales of 550 pounds each.

The forests of Congo are of great value, but difficult of exploitation, due to lack of transportation facilities. With proper facilities the Congo should be able to export great quantities of wood for all purposes. In 1917 the export of woods of all kinds amounted only to 44 tons.

The great mining wealth of the Congo is being rapidly developed, and the production of gold, copper, and diamonds is constantly increasing. In the diamond mines, located in the Province of Kasai, the output in 1914 was 23,837 carats; in 1915, 48,924 carats; in 1916, 53,941 carats. In the year 1917 the production almost doubled the 1916 output, being 99,960 carats.

The production of gold in the mines around Kilo and Moto in the Ituri District, has also been increasing rapidly. The annual production since 1914 is as follows, in troy ounces: 1914, 55,084; 1915, 83,929; 1916, 95,892; 1917, 113,725; 1918 (first 7 months), 102,040.

The war acted as a great stimulus on the copper-mining industry in the Kongo. In 1918 there were seven furnaces in operation around Elisabethville, capable of an annual output of 40,000 tons of copper. Since 1913 the production has almost quadrupled, as shown by the following statistics: 1913, 7,048 metric tons; 1914, 10,722 tons; 1915, 14,054 tons; 1916, 22,149 tons; 1917, 27,462 tons. The Province of Katanga is thus becoming one of the large copper-producing regions of the world. New mines are being extended and developed.

While the war stimulated the export trade of the Kongo, it caused stagnation in the import trade. In 1913 the value of the imports amounted to some £3,500,000; in 1917 the value had fallen to about £2,800,000.

A general idea can be had of the import needs of the Kongo from a survey of the 1917 statistics. Noticeable among the imports are foodstuffs that cannot be produced in the country, or the production of which has not yet been developed, raw materials necessary to industrial development, and manufactured products of all kinds. The industrial growth of the Kongo is shown in the demand for iron and steel products, railway material, and machines and tools. The Kongo has reached a stage in its development where the need of better and quicker methods of doing work, and better transportation facilities, is being keenly felt, and imports of all kinds of machines and tools, and railway materials should increase rapidly.

SANTONIN.

Some years ago the Government of India appointed a Drugs Manufacture Committee. Many drugs which were formerly imported are now being obtained from Indian-grown materials. Dr. J. L. Simonsen, of the Forest Research Institute and College, Dehra Dun, writing in the "Journal of Indian Industries and Labour," calls the attention of the Committee to a possible further and important development, namely, the extraction of santonin from *artemesia maritima* grown in Kashmir. He is of opinion that the plant grown there contains enough santonin to be remunerative, and, from the information available, he says there would appear to be sufficient supplies of the raw material. It now only remains for the laboratory results to be utilised on the large scale. The method of extraction is comparatively simple, and the only chemicals required are lime, hydrochloric acid and alcohol, all of which are

readily obtainable in India. As the leaves are bulky, the factory, it is suggested, should be in Kashmir, but as a preliminary arrangement might be made for extraction at the Medical Stores in Lahore.

The drug occurs in the young flower heads of *artemesia maritima* and finds an extensive use in medicine as a vermifuge. Prior to the war practically the whole of the world's supply came from Russian Turkestan, where the flower heads were gathered and the drug extracted. It has not been possible to obtain any recent data as to the size of the industry, but the area under *artemesia maritima* must have been considerable, since in 1885 one factory dealt with 1,600 tons of the flower heads. At that date there were apparently at least two other factories, but no information is available as to their output. The industry was conducted in a somewhat primitive fashion; the plants were pulled by the nomad inhabitants of the district, who stripped off the flower heads and used the remainder of the plant as fuel.

At this time the value of the santonin was estimated at £2 to £3 per kilo., but it could apparently be sold in Hamburg with a profit at 18 shillings a kilo. As a result of the unsettled conditions prevailing in Russian Turkestan no santonin is now being placed on the market, and the present price stands at the amazing figure of £50 per kilo. It is obvious, therefore, that some other source of supply of this valuable drug must be sought if adequate supplies are to be available once more.

GENERAL NOTES

THE CAMBRIDGE SCHOOL OF ARCHITECTURE.—A number of architects who are old Cambridge men have just formed a Club with a view to helping, wherever possible, the work of the Cambridge School of architecture. As a first step they have agreed to double the donation of £50 given this year by the R.I.B.A. to the funds of the School, and they propose in future to meet once a year, either in Cambridge or London, to establish relations with the staff of the School and to keep in touch with its work generally. Mr. Maurice E. Webb, F.R.I.B.A., has been elected Chairman of the Club and Mr. J. Alan Slater, A.R.I.B.A., Hon. Secretary and Treasurer.

THE FUEL RESEARCH BOARD.—It has long been felt that an important aspect of the great problem of the conservation of the national coal resources involves the study and classification of the coal seams which are at present being worked or developed, and also of seams or portions of seams which are being left unworked or are thrown aside above or below ground. This study and classification on its directly practical side must deal primarily with the

suitability of each particular coal for those purposes for which its individual qualities render it most adequate, e.g., for gas making, coke making, steam raising or for domestic use. This question of survey has for some years been receiving the anxious consideration of the Fuel Research Board, but the unstable conditions which prevailed in the coal industry during and since the war have necessarily led to the postponement of the work of organisation. It is now, however, considered that the time has arrived when a beginning can wisely be made. The Fuel Research Board believe that this work can be most effectively carried out with the help of local Committees in which colliery owners, managers and consumers are associated with the representatives of the Fuel Research Board and the Geological Survey. By this combination not only will local knowledge and experience be made available, but the initiative of those most deeply interested in the practical aspects of this survey will be secured. The survey work will thus from the outset assume a practical character, for the selection of seams for examination will be in the hands of those who are in the best position to estimate the relative importance of the problems awaiting solution. The selected seams will be submitted to physical and chemical examination by the local experts; and, as a result of this examination, a further selection will be made of those which appear to justify experiments on a practical scale to test their suitability for particular uses or methods of treatment. This experimental work will be carried out either at H.M. Fuel Research Station, or at other works, as may be found most convenient. The first Committee is already actively at work in the Lancashire and Cheshire district, where the local Research Association has been recognised by the Fuel Research Board as its representative body for the purpose. It is felt by the Fuel Research Board that the experience gained in the work and organisation of this Committee will be of great value in the establishment of Committees in other districts when the time is ripe for further developments, but they are satisfied that it will be wise to build up this national organisation on the sure foundations of actual experience.

THE INDIAN ANTIQUARY.—To celebrate the fiftieth anniversary of the publication of the "Indian Antiquary," Sir Richard Temple, Bt., who for thirty-seven years has been the Editor-Proprietor, has written a short account of the history of the magazine, which has had among its contributors many great Indian and Oriental scholars in India itself, as well as all over Europe and America. The object of the "Indian Antiquary" has been to provide a means of communication between the East and the West on subjects connected with Indian research, and a medium to which students and scholars, Indian and non-Indian, could

combine to send notes and queries of a nature not usually finding a place in the pages of Asiatic societies. The main aim has been to promote and encourage research. The subjects with which the magazine has been principally concerned have been the Archaeology, Epigraphy, Ethnology, Geography, History, Folklore, Language, Literature, Numismatics, Philology, Philosophy, and Religion of the Indian Empire, and, to a certain extent, of its surroundings. Notable contributions have been published on all these subjects, several of them having been preliminary studies of books subsequently well known to Indian and Oriental students, and even to general fame

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 p.m. :—

FEBRUARY 15.—**CLOUDESLEY BRERETON**, M.A., Divisional Inspector to the London County Council (Modern Languages), "The Necessity of Speech Training, and the Need of a National Conservatoire." **SIR HENRY NEWBOLT**, C.H., D.Litt., LL.D., Chairman of the Departmental Committee on the Teaching of English, in the chair.

FEBRUARY 22.—**ALEXANDER SCOTT**, Sc.D., D.Sc., M.A., F.R.S., "The Restoration and Preservation of Objects at the British Museum." **SIR ASTON WEBB**, K.C.V.O., C.B., P.R.A., in the chair.

MARCH 1.—**EMANUEL MOOR**, "The Duplex-Coupler Pianoforte." **PERCY A. SCHOLLS**, Music Critic to the *Observer*, in the Chair.

MARCH 8.—**W. A. APPLETON**, C.B.E., Secretary to the General Federation of Trade Unions, "The Proper Functions of Trade Unions." **JOHN MURRAY**, M.P., in the chair.

MARCH 15.—**OSWALD T. FALK**, "Certain Aspects of the Problem of Exchange Stabilisation." **SIR ROBERT M. KINDERSLEY**, K.B.E., in the chair.

MARCH 22.—**PRINCIPAL A. P. LAURIE**, M.A., D.Sc., F.R.S.E., "The Permanency of Oil Colours." **SIR ASTON WEBB**, K.C.V.O., C.B., P.R.A., in the chair.

MARCH 29.—**SIR THOMAS OLIVER**, LL.D., D.Sc., M.D., F.R.C.P., "Alcohol in Relation to Industrial Hygiene." (Shaw Lecture.)

APRIL 5.—**PROFESSOR ERNEST R. MATTHEWS**, "Sea Encroachment and its Prevention." **LORD HEADLEY**, M.Inst.C.E.I., in the chair.

APRIL 26.—**JOHN FRANCIS CROWLEY**, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry."

SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the chair.

Dates to be hereafter announced :—

LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

PHILIP SCHIDROWITZ, Ph.D., F.C.S., "Recent Developments in India Rubber Manufacture."

MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock.

MARCH 24.—PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India."

APRIL 28.—F. G. ROYAL-DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the chair.

MAY 26.—PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow, Magdalene College, Cambridge. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced :—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons, at 4.30 o'clock.

MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E., "Tanganyika Territory (formerly German East Africa)." Date to be hereafter announced.

LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON G.B.E., K.C.M.G., "New Zealand." Date to be hereafter announced.

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETINGS.)

Friday afternoons, at 4.30 o'clock.

FEBRUARY 24.—PROFESSOR WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S., "Brown Coals and Lignites: Their Importance to the Empire." VISCOUNT ELVEDEN, C.B., C.M.G., M.P., in the chair.

MAY 5.—PROFESSOR WILLIAM HENRY ECCLES, D.Sc. (London), F.R.S., "Imperial Wireless Communication."

CANTOR LECTURES.

Monday evenings, at 8 o'clock.

ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., late Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington, "The Mechanical Design of Scientific Instruments." Three Lectures. February 20, 27 and March 6.

Syllabus.

LECTURE I.—FEBRUARY 20.—Design from the point of view of the User and the Manufacturer—Clerk Maxwell's axioms of Instrument Design—Degrees of Freedom and Constraint—The Six Degrees of Freedom of a Rigid Body—Geometric Design.

LECTURE II.—FEBRUARY 27.—The Lower and Higher Pairs—Restraint against Sliding—Restraint against Rotation—Centroids and Axodes—The Design of Profiles.

LECTURE III.—MARCH 6.—The Elastic Nature of all Materials—The Elastic Constants—The Rigidity of Instruments—Manufacture—Models—Interchangeable Manufacture.

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester. "The Constituents of Essential Oils." Three Lectures. March 20, 27, April 3.

COBB LECTURES.

Monday evenings, at 8 o'clock.

F. F. RENWICK, F.I.C., F.C.S., A.C.G.I., "Modern Aspects of Photography." Three Lectures. May 1, 8, 15.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, FEBRUARY 13.—Health, People's League of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Dr. R. H. Cole, "Sensation, Perception, Idealism and Attention."

Geographical Society, Lowther Lodge, Kensington Gore, S.W., 5 p.m.

Electrical Engineers, Institution of (North-Eastern Centre), Armstrong College, Newcastle, 7.15 p.m. Mr. F. P. Whitaker, "Rotary Converters, with special reference to Railway Electrification." (Dundee Sub-Centre), University College, Dundee, 7.30 p.m. Mr. J. W. Beauchamp, "Publicity and Electrical Development."

Faraday Society, at the Chemical Society, Burlington House, Piccadilly, W. (1) Prof. J. R. Partington, "The Energy of Gaseous Molecules." (2) Mr. U. R. Evans, "Reactivity and Over Potential." (3) Prof. A. W. Porter, "Note on the Vapour Pressure of Ternary Mixtures."

Transport, Institute of, at the Institution of Civil Engineers, Great George Street, S.W., 5.30 p.m. Sir Henry White-Smith, "The Development of Commercial Airways."
Chemical Industry, Society of (Glasgow Section), 39, Elmbank Crescent, Glasgow, 7.15 p.m. Mr. D. N. McArthur, "Some Chemical Problems in Agriculture."

TUESDAY, FEBRUARY 14. Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. J. E. Hachford, "The Significance of the Interpretation of the Chemical Analyses of Seepages."

Rubber Industry, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.45 p.m.

Anthropological Institute, at the Royal Society, Burlington House, Piccadilly, W., 8.15 p.m. Prof. G. E. Smith, "The Brain of Rhodesian Man."

Asiatic Society, 74, Grosvenor Street, W., 4.30 p.m. Colonel T. C. Hodson, "Head Hunters at Home."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Dr. Horn, "The Belgian Congo Administration in the Congo and the Mandatory Territory."

Dyers and Colorists, Society of (West Riding Section), Mr. F. E. Lamplough, "Artificial Daylight."

British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. R. A. Dawson, "Celtic Art—its Development in Christian and Pre-Christian Times."

University of London, at the London School of Economics, Houghton Street, Aldwych, W.C., 6 p.m. Sir Josiah Stamp, "The Administrative Factor in Government." (Lecture I.)

Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Colonel T. C. Hodson, "The Primitive Culture of India." (Lecture IV.)

Metals, Institute of, Chamber of Commerce, New Street, Birmingham, 7.30 p.m. Prof. F. C. Lea, "Light Aluminium Alloys." (Scottish Section), 39, Elmbank Crescent, Glasgow, 7.30 p.m. (1) Mr. J. A. Sillars, "The Production of Lead Pipes by the Extrusion Method." (2) Mr. H. J. Brand, "The Smelting and Refining of Zinc."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. H. H. Turner, "Variable Stars." (Lecture III.)

Electrical Engineers, Institution of (East Midland Sub-Centre), The College, Loughborough, 6.45 p.m. Discussion on "Mercury-Arc Rectifiers." (Scottish Section), 207, Bath Street, Glasgow, 7.30 p.m. Major J. Erskine-Murray, "The Use of Wireless, Past and Present." (North Midland Section), Hotel Metropole, King Street, Leeds, 7 p.m. Messrs L. J. Steele and H. Martin, "The Cyc-Arc Process of Automatic Electric Welding."

Textile Institute, 16, St. Mary's Parsonage, Manchester, 4 p.m. Mr. W. Bailey, "Recent Developments in Winding and Doubling."

Photographic Society, 35, Russell Square, W.C., 7 p.m. (Technical Meeting). (1) Prof. Dr. T. Svedberg (a) "On the relation between the Size of Grain and Sensitivity of Photographic Emulsion (Part II); (b) The Reducibility of the Individual Haloid Grains in a Photographic Emulsion." (2) Mr. K. C. D. Hickman, "An Optical Method of Testing Washing Devices, together with a Demonstration of some Wasting Devices."

Transport, Institute of (North-Western Section), The University, Liverpool, 5.30 p.m. Mr. F. E. Bixandale, "Some Notes on Railway Operations, Past, Present and Future."

WEDNESDAY, FEBRUARY 15. African Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Sir Robert Coryndon, "Problems of Eastern Africa."

Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Dr. L. D. Barnett, "The Jews."

Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Dr. M. S. Paterson, "The Success and Failure of Sanatoria Treatment."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Sir George Paish, "Industry and its Relation to Finance."

Meteorological Society, 49, Cromwell Road, S.W., 7.30 p.m.

Microscopical Society, 28, Hanover Square, W., 8 p.m. Mr. A. L. Booth, "The Microstructure of Coal from an Industrial Standpoint."

Royal United Service Institution, Whitehall S.W., 3 p.m. Colonel-Commandant L. C. L. Oldfield, "Artillery and the Lessons we have learnt with regard to it in the Late War."

Electrical Engineers, Institution of (Sheffield Sub-Centre), Royal Victoria Hotel, Sheffield 7.30 p.m.

THURSDAY, FEBRUARY 16. Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Sqdr.-Ldr. C. F. A. Portal, "Methods of Instruction in Aeroplanes Flying."

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Royal Society, Burlington House, Piccadilly W., 4 p.m.

Royal Institution, Albemarle Street, W., 3 p.m. Prof. A. G. Perkin, "Dyeing—Ancient and Modern." (Lecture I.)

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. Mr. F. P. Whitaker, "Rotary Converters with special reference to Railway Electrification."

Constructive Birth Control and Racial Progress Society for, Essex Hall, Essex Street, Strand W.C., 8 p.m. Mr. E. B. Turner, "Sex Relations."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Chemical Society, Burlington House, Piccadilly W., 8 p.m. (1) Mr. A. W. Lapworth, "A Theoretical Derivation of the Principle of Induced Alternate Polarities." (2) Messrs W. O. Kermack and R. Robinson, "An Explanation of the Property of Induced Polarity of Atoms and an Interpretation of the Theory of Partial Valencies on an Electronic Basis."

Auctioneers' and Estate Agents' Institute, 34 Russell Square, W.C., 7.30 p.m. Mr. C. H. Closs, "Mortgage Valuations."

China Society, at the School of Oriental Studies, Finsbury Circus, E.C., 5 p.m. Miss E. G. Kemp, "Some Aboriginal Tribes in China."

FRIDAY, FEBRUARY 17. Transport, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Colonel J. A. Saner, "British and Foreign Canals and Waterways Compared."

Japan Society, 20, Hanover Square, W., 5 p.m. Royal Institution, Albemarle Street W., 9 p.m. Dr S. M. Watson, "History of the Mammalian Ear."

Metals Institute of, The University, Sheffield 7.30 p.m. Joint Meeting with the Institution of British Foundrymen.

University of London, King's College, Strand W.C., 5 p.m. Prof. R. Robinson, "Orientation and Conjugation in Organic Chemistry from the Standpoint of the Theories of Partial Valency and the Latent Polarity of Atoms." (Lecture II.)

Geological Society, Burlington House, Piccadilly W., 3 p.m. Annual General Meeting. Address by the President.

Photographic Society, 35, Russell Square, 8 p.m. Address by Prof. Rothenstein.

Mechanical Engineers, Institution of, 6 p.m. (1) Annual General Meeting. (2) Mr. A. T. Wall, "Electric Welding applied to Steel Construction with special reference to Ships."

Chemical Industry, Society of (Liverpool Section) The University, Liverpool, 6 p.m. Prof. I. M. Heilbron, "The Photosynthesis of Plant Products."

Engineers, Junior Institution of, Caxton Hall Westminster, S.W., 8 p.m. Mr. W. J. Leaton, "Water Purification for Boiler-Feed Purposes."

SATURDAY, FEBRUARY 18. Royal Institution, Albemarle Street, W., 3 p.m. Prof. E. A. Gardner, "Masterpieces of Greek Sculpture." (Lecture I.)

Chromatics, International College of, Caxton Hall, Westminster, S.W., 3.15 p.m. Mr. F. C. Reynolds, "An Experimental Demonstration of the Colours produced by Polarized Light."

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday of the week preceding the Meeting.

*For Meetings of the ROYAL SOCIETY OF ARTS, see page 22.

No. 3.613

VOL. LXX.

FRIDAY, FEBRUARY 17, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 20th, at 8 p.m. (Cantor Lecture.) ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington, "The Mechanical Design of Scientific Instruments." (Lecture I.)

WEDNESDAY, FEBRUARY 22nd, at 8 p.m. (Ordinary Meeting.) ALEXANDER SCOTT, Sc.D., D.Sc., M.A., F.R.S., "The Restoration and Preservation of Objects at the British Museum." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., in the chair.

FRIDAY, FEBRUARY 24th, at 4.30 p.m. (Joint Meeting of Dominions and Colonies and Indian Sections.) WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S., Professor of Chemical Technology, Imperial College of Science and Technology, "Brown Coals and Lignites: Their Importance to the Empire." VISCOUNT ELVEDEN, C.B., C.M.G., M.P., in the chair.

ELEVENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 8th, 1922 ; Mr. W. J. U. WOOLCOCK, C.B.E., M.P., in the chair.

The following candidates were proposed for election as Fellows of the Society :—Gidney, Lieut.-Col. Henry A. J., F.R.C.S., D.P.H., J.P., M.L.A., I.M.S. (retired), Delhi, India.

Khan, Ghulam Mohd, Lyallpur, India.

The following candidates were balloted for and duly elected Fellows of the Society : Beadle, Ormond Alec., Oxford.
Chettiar, Rao Sahib P.K.A.C.T. Veerappa, M.B.E., Kottaiyur, Madras, India.
Oppenheimer, Maurice, Rangoon, Burma.
Taylor, Samuel Daniel, Oxford.

A paper on "Some Solved and Unsolved Problems in Gas Works Chemistry," was read by Mr. EDWARD VICTOR EVANS, O.B.E., F.I.C., Chief Chemist, South Metropolitan Gas Company.

The paper and discussion will be published in the *Journal* of March 10th.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

FRIDAY, JANUARY 27TH, 1922.

SIR WILLIAM S. MEYER, G.C.I.E., K.C.S.I. (High Commissioner for India), in the chair.

THE SECRETARY OF THE SECTION announced that the Secretary of State for India was unable, to his very great regret, to fulfil his promise to take the chair at the meeting, owing to urgent public business, but the High Commissioner for India had most kindly consented at very short notice to take Mr. Montagu's place. Mr. Montagu had sent a message to say that he had been looking forward with great pleasure to the meeting, and it was a great disappointment to him that the exigencies of public life prevented him from being present.

THE CHAIRMAN said he must ask the meeting to accept him as a very inadequate substitute for Mr. Montagu, whose absence had been explained by the Secretary. Personally, he knew that Mr. Montagu very much wanted to attend the meeting, but even Cabinet Ministers were not their own masters nowadays, and Mr. Montagu was one of the victims of the Cabinet habit. The author of the very interesting paper on "The Timbers of India and Burma" to be read at the meeting was his friend, Mr. Alexander Howard, who was one of the greatest living authorities on the subject. He was the head of one of the great timber firms of the Empire, and was also a writer on the subject. He had written a most valuable manual on the timbers of the world, and had from time to time written most interesting brochures on some of the timbers of India. Mr. Howard had

a very special connection with India, because for the last few years his firm had been the Agents for the Government of India and the Provincial Governments in connection with the sale of Indian timbers and articles made from them in this country. In that capacity Mr. Howard had rendered very great service, and although his modesty had prevented him from saying so in the paper, the developments that were mentioned were very largely due to his personal initiative and knowledge. Mr. Howard also took a very great share in the splendid representation of Indian timbers at the Empire Timber Exhibition in 1920. Probably a good many of those present visited that Exhibition, and they must have been very much gratified by the prominent part that India took there. Mr. Howard and himself had come into close official contact, because under the system of "dyarchy," which now prevailed in London as well as in India, in regard to Indian affairs, the dyarchs in this country being the Secretary of State and the High Commissioner, he had taken over the supervision of the work of Mr. Howard's firm in connection with the sale of Indian timbers. He had found him a most genial and efficient comrade, and desired to express the great obligations he was under to him in the decoration of the offices at Grosvenor Gardens. The panelling and flooring of some of the public rooms there were to be done in Indian timbers, and the furniture was to be made of Indian wood. Each room would have a special scheme: there would be a padauk room, a laurel-grey room, and so on. Mr. Howard had given most valuable advice on the subject and was very keen about it, because he rightly argued that it was not a mere question of æsthetic decoration, but of commercial expediency. Every now and then people came to Mr. Howard, and when he recommended them to furnish rooms with Indian woods and furniture, they said it was impossible for them to judge what could be produced from the specimen slabs of wood that were exhibited, and that they would like to see how a room panelled and floored with Indian woods would look. In future Mr. Howard would be able to send such people to the High Commissioner's offices in Grosvenor Gardens, where they would be able to see rooms so fitted, and it was hoped in that way that the market for Indian timbers in this country would be very considerably developed. Unfortunately, Mr. Howard was not present to read his paper, as he had had to leave England on urgent business, and in his absence it would be read by his kinsman, Mr. A. A. Hannay, while the views that would be shown on the screen would be explained by Sir George Hart, late Inspector-General of Forests to the Government of India.

MR. HANNAY, before reading the paper, said he was desired by Mr. Howard to express his

deep regret that he was unable to appear in person in recognition of the distinction conferred upon him in being invited by the Society to read a paper on a subject in which he was so deeply interested.

The paper read was :—

THE TIMBERS OF INDIA AND BURMA.

BY ALEXANDER L. HOWARD.

To-night I am to address you upon the timbers of India and Burma, and I must confess to have felt some little anxiety as to the manner in which I am to treat this subject before so distinguished an audience.

My friend, Mr. H. J. Elwes, of Colesborne, speaking after Professor Troup's lecture last January, said he hoped that it would be followed by one written from the commercial side, which would give an idea of what was practicable from that stand-point. This is important, for, after all, one of the chief aims in the prosecution of a scientific forest policy is to make the forests yield the highest possible sustained revenue for the owner; in other words, always provided that the upkeep of the forest estate is assured, the object in view is commercial and practical.

It is, therefore, as one with a practical experience of timber and its uses, and with a knowledge of the timber market, that I have been invited here to-day. In addition to this double equipment, I may perhaps speak with further confidence about Indian timbers, since within this last year I have made an extended tour through some of the chief timber-producing areas of India, Burma, and the Andaman Islands, with the object of gauging their possibilities for the development of trade.

Consequently, in considering my paper beforehand, I have been guided by the aim of supplementing the knowledge of forestry and the botanical structure of wood which many of you doubtless possess in a large degree, by my commercial and practical experience. We are anxious to bridge over the gulf, still too apparent, between abstract science and commercial activity. An appreciation of the needs, the difficulties and the problems of the industrial world must guide the trend of scientific research, if industry and science are to further their mutual interests.

I think that in England this point still requires emphasising. We want this mutual dependence of science and trade to be more generally recognised, and we need to modify our industry by scientific knowledge and method. Important points about wood, such as durability, colour, grain, and possible uses—often dismissed as of trade interest only—are as worthy of attention and as worthy of a place in the complete understanding of a wood, as are the purely botanical aspects. Indeed, a scientific knowledge of wood which ignores these points is one-sided and does not justify its name, for science in its widest significance embraces observed phenomena of all kinds.

That the importance of this point with regard to these woods has already been recognised in India is proved by the work done at the Research Institute at Dehra Dun, and, again, may be seen by the Report of the Indian Industrial Commission which was published in 1919, in which the exploitation of the forests on more commercial lines, and the necessity of commercial methods in rendering their products available for industrialists, is imperatively insisted on, and this is what I also wish to emphasise to-night.

No one who has seen the furniture and other works in Indian woods as they have been produced here by our English craftsmen can fail to appreciate their great beauty and distinction. Still, from the point of view of timber consumers in this country, the chief considerations are purely practical factors, such as the f.o.b. (the "free on board") price, the cost of freight, and whether there is a sufficiency of the timber to guarantee steady and continuous supplies.

My experience in the trade has forced me to the conclusion that in many timber-producing countries, particularly in the tropics, the timbers which are most esteemed by local inhabitants often prove to be the least valuable for export. On the other hand, timbers which are of little use in the country of their origin are not seldom of great importance in parts of the world with different climatic conditions. Thus it is unlikely that the deodar and the sal, which are the principal timbers of Northern and Central India, would be successful in British and European markets, while woods such as Indian white mahogany, laurel-wood, gurjun, white bombwe, silver greywood and white chuglam, all of which may be expected

to prove of very considerable value in home markets, are in small demand in India. The consequence of this is that the majority of Indian timbers likely to be appreciated by consumers in Europe are, in default of any large local demand, obtainable at a price far below their intrinsic value, and so the f.o.b. price for these timbers is, for the present at all events, very advantageous to the buyer.

Then there is the cost of freight. Since the Armistice, freights, which during the war and immediately after soared to a point previously unknown, have become more and more reduced till now they are often less than they were before the war. Shipping freight cost is always rather a speculative affair, and undoubtedly if it were to go up again to anything approaching that of the war years, the trade in the timbers of India and Burma would be very adversely affected, though even in such a case, I do not think it would be utterly ruined. However, it does not appear that there is the slightest prospect of any material change from present conditions for some time to come.

I was able, when in India, to lay the foundations of a scheme which has since enabled us to have direct shipment of timber from Indian and Burmese ports, and from the Andaman Islands. Altogether some five or six ships have been employed during the last few months, one of which is now loading at Rangoon. The first ship to be so utilised was the ss. "Rhodesia," which arrived at the West India Docks from Rangoon in August last, with a full cargo from the Government of Burma of fine teak logs of large size. This import of round teak logs has given rise to an animated discussion in the technical press on the comparative advantages of bringing the timber over as it comes from the forest, instead of in sawn squares, which is the form in which teak has been imported in the past. I do not intend to trouble you further on this subject, except to say that while at the start I believed that the import of round logs would be beneficial both for the producer and the consumer, I am now convinced by experience of the advantage of marketing the timber in this form.

With regard to the sufficiency of the timber supply, there is no question as to this, when you realise that the Government forests occupy an area of 251,000 square miles. Reflect for a moment that the whole

FIG. 1.—Teak Logs on Dragging Path. Prepared with Cross Billets.

area of Great Britain is 88,000 square miles, and that in India and Burma there are 251,000 square miles of forest.

There remains one element to be considered: and this is, whether the Government of India, through the officers of the Forest Service, will continue the energetic and progressive policy which they have lately adopted. Of the efficiency of the Indian Forest Service it is quite unnecessary for me to speak to you here to-night, for it will be known to you all and is beyond question. All Governments and Government servants, however, are at some disadvantage in carrying out any commercial enterprise, and the local Governments of India and Burma are no more free from this disability than any others.

I would, therefore, earnestly direct the attention of the authorities concerned to the paramount necessity of obtaining a thorough grasp of the commercial conditions in Europe, so that they may realise, for instance, the importance of producing their timber for the market in the manner and in the quantities which are required by the buyers. Only by such a proceeding will it be possible to garner the immense harvest of revenue which is available, but which is

so absolutely dependent upon this point.

Personally, I am convinced that it is only by actual Government initiation and exploitation that these timbers can be brought into common use. For many years Government have endeavoured to encourage private trading firms to exploit these lesser-known native timbers, but they have so far met with little success, and I do not think they will meet with much more in the future. The whole problem suggests itself as too complicated and hazardous an enterprise for any private, or public, corporate trading concern to undertake, until it has been established by the Government on a firm and substantial basis. It may be argued that both Government assistance and co-operation in forest industry have been largely dispensed with in other countries, and that this might well be so in India. The answer to this is that in most countries where private enterprise in forest industry has been pre-eminently successful there has been unlimited freedom and independence of action throughout the industry. In British India, however, the forests are the property of Government, and Government is pledged to manage them with the object, not only of maintaining them in their

present condition, but of improving them to the greatest possible extent in the interests of future generations. Unlimited freedom of action for private enterprise is, therefore, impossible in India. I am convinced that the great expense to which the Government of India have been put, and the advantages which have already been gained in the development of this industry, will all be of no effect unless the considerations which I have outlined are borne in mind.

I am afraid that the economic use of timber, with which is bound up its suitability for various industrial purposes, is better understood elsewhere than it is in England. Our hide-bound repetition of the use of oak, mahogany and walnut has become almost ludicrous in face of the wide field of choice that now lies before the artist, the architect, and the craftsman. It is this circumscribed outlook which causes a wood to continue in demand long after the original reason for its adoption—

FIG. 2.—Eng, Lower Burma;

cheapness, abundance of supplies or what not—has ceased to exist. I have just returned from a tour through France, Germany, Holland and Belgium, and I found that existing conditions practically limit the use of timber in these countries to home products, for the adverse rate of exchange makes any other course too extravagant. Yet I found a better knowledge and understanding of the woods used than exists in this country; for the woods are chosen, firstly, with due regard to the needs and resources of the country, and secondly, on their own actual merits for the specific purpose in view. I might say, however, that in my experience the English wood-working craftsman stands supreme in the results which he can achieve.

Here in England it seems to be our custom to belittle the value both of home and of Empire grown timber, with the result that foreign woods have been exploited to the detriment of our own. While this is a questionable policy from the patriotic point of view, it is also certainly near-sighted and indefensible economically, for it tends to force the price of the timber to a point beyond its natural value. A noteworthy and commendable exception may be noticed in the action of the Bank of England, which, notwithstanding considerable opposition from various quarters, has had the whole of the decorative wood-work in its new buildings in Finsbury Circus made of Indian timbers. This example has been followed by many others, and amongst the works recently completed in these woods I may mention the following:—

London County Hall (Holland & Hannen & Cubitts, Ltd.) — Laurel-wood panelling.

Francis Peek & Co., Eastcheap (Holland & Hannen & Cubitts, Ltd.)—Padauk, laurel-wood, silver greywood and gurjun panelling and fittings.

Blade, East & Blade, Cannon Street, London—Silver greywood fittings.

Guardian Assurance Co., London (Higgs & Hill, Ltd.)—Laurel-wood and koko panelling and fittings, gurjun block flooring (Stanhope Flooring Co.).

General Electric Co., Birmingham (Elliott & Sons, Reading)—Silver greywood panelling, silver greywood lift (Express Lift Co.).

Bovis, Ltd., London—Padauk panelling (Bovis, Ltd.).

Mr. Llewellyn, Gloucester (Elliott & Sons) —Rosewood panelling.

Barclay's Bank, Palmers Green (Stapleton & Co.)—Padauk fittings.

Great Eastern Railway Co.—Silver greywood and padauk Pullman car fittings.

Great Eastern Railway Co. Showrooms—Silver greywood parquet flooring.

Clan Line Steamships (A. J. Norris & Co.) —Padauk panelling and fittings.

Spink & Co., London—Showroom and warehouse gurjun flooring.

Reading Corporation Tramways—White mahogany tram-car panelling.

Emanuel & Co.—Bedroom suites in white mahogany.

Coals, Lovell & Co.—Dining room suites in white mahogany.

Robersons, Ltd.—Dining tables in padauk. Caffall & Co.—Chairs in koko.

Burroughes & Watts—Billiard tables in padauk.

Cramer & Co.—Pianofortes in white mahogany (cases).

To give you an idea of how small the Indian timber imports have been in the past, I may mention that in 1913, a typical pre-war year, the value of the timber imported into the United Kingdom amounted to £33,788,884, of which only £739,515 was due to India, teak accounting for 94 per cent. of India's share. During last year Indian timber imports largely increased, though complete statistics are not yet available.

There are nearly 2,500 different species of timber trees to be found in India, Burma, and the Andaman Islands. Only a small proportion of these are of economic interest, and very few of them were known to timber buyers in England before the Empire Timber Exhibition of 1920. The qualities of these woods are not very well known in India either, for, strangely enough, in the teak-bearing tracts timbers are generally described as "teak and jungle-woods." This derogatory term "jungle-woods" is, of course, detrimental to the trade. It is, also, an unmerited slur, and an absurd depreciation, for among these so-called jungle-woods we have found logs the individual value of which has exceeded that of the finest mahogany or satin-wood: moreover, there has recently been discovered among them a wood which equals, if it does not exceed in value, any boxwood which the world can produce.

- In the short space of time at my disposal to-night, it is impossible to deal adequately with this great variety of woods, and I must content myself with speaking of a very few of the most noteworthy, though I have here a number of panels of various Indian woods which I think you will find worth examination. That such excellent results can be achieved will, I fancy, surprise you, and more particularly, perhaps, those of you who may be familiar with the timbers of India only in their native country and when prepared by native craftsmen.

LAUREL-WOOD.

Though from a very early date walnut has been used for furniture and decorative work throughout Europe, it seems to me undesirable that works of art, whose beauty makes them worthy of permanence, should be executed in walnut, for this wood is almost invariably attacked by boring beetles, which ultimately destroy the whole fabric. The artistic appearance given by the warm tones and fine figure of walnut is one of the principal reasons for its selection. The Indian laurel-wood provides this

FIG. 3.—Sideboard in Laurel Wood and Red Zebra Wood.

also in a superlative degree and is, I venture to say, the most beautiful wood that India can provide. Its durability, in contrast to walnut, for which it will be an excellent substitute, may, in my opinion, be regarded as beyond question.

GURJUN.

Those who wish to see a beautiful example of work in this wood, and, by the way, of laurel-wood and of padauk also, should ask for permission from the firm of Messrs. Francis Peek & Co. to visit their building

in Eastcheap, where there is some fine gurjun panelling. Among other instances of the use of this timber I may mention the flooring recently put down in the new Bank of England building in Finsbury Circus; the ball-room floor laid 15 years ago for Mr. Trevor-Battye, who tells me that it is admired by all who see it; and the railway coach constructed by the Great Eastern Railway Co., which has proved so satisfactory that other leading railway companies are now using this timber for coach work.

FIG. 4.—Indian Silver Greywood Cabinet.

One of the great advantages of this timber is that it is available in very long lengths and large sizes, free from any defect, while as the result of breaking-tests which have been made it has proved to be stronger than British oak. One of my friends who has tested gurjun for breaking strain has brought to light rather a curious fact. It was found that not in one single test was it possible to break the wood right through so that one piece was severed from the other. In each instance two pieces continued to be jointed together by what appeared to be a tough outer skin which thus formed a kind of hinge.

I would like to add one word in connection with this wood, and that is that it should never be used for joinery, carpentry, or any other work of importance, unless it is thoroughly seasoned; also that whenever possible it should be sawn on the quarter. When cut on the tangential section it is liable to shrink and warp, and this is particularly noticeable if the wood be not completely seasoned.

INDIAN SILVER GREYWOOD.

This is a beautiful wood, but it needs careful selection according to the use for which it is required. Supplies can be obtained which display a uniform grey shade with a tinge of green in it and a beautiful silvery lustre; others have varying streaks of lighter and darker colouring, while occasionally very varied and wild marking is seen. It is desirable that the wood be selected by the craftsman, so that the completed work may present a harmonious effect, and not a medley of different variations, which, though in themselves very beautiful, mar the effect when placed in juxtaposition. The specimens of panels and of parquet flooring in silver greywood which are shewn here will give you an opportunity of seeing how this selection ought to be made. With exposure to the air the colour improves, though it is inclined to darken slightly. One great recommendation of the wood is that the colour is permanent, in which respect it is unlike the so-called "greywood," which is stained sycamore, that is so much in use.

In addition to those works in silver greywood of which I have previously made mention, it has been used for parquet flooring in a number of private houses. Some very beautiful furniture was also made of this wood for the Exhibition, and

it may be said that there is a great future before it.

PYINKADO.

This is the ironwood of Burma. I measured a tree in the forest which had a clear stem of 50 feet to the first branch and at breast height it girthed 17 feet 3 inches, which is equal to a diameter of approximately 5 feet 9 inches, and the trees commonly grow to a height of 90 to 100 feet.

If the pyinkado had grown in America, I venture to say that the whole world would have heard of its wonderful qualities of strength and durability. Lieut.-Col. Blake, Commissioner at Moulmein, writing in 1875, said that the wood was heavier than water and more indestructible than iron, while the teredo would not touch it. He added:—"There is a piece of this wood which supported a teak figure of Godama, taken from Rangoon in 1826, standing in a lake near. The teak figure has long since mouldered away into dust, but at the pillar I fired a rifle shot at 20 yards distance; the ball was thrown back, making no penetration whatever." What a wonderful tribute this is to the durability of pyinkado! If the teak figure had "long since mouldered away into dust," how old must the standard have been?

Though this timber is very hard it can be sawn and worked without much difficulty when comparatively fresh.

PADAUK.

Much as I know of the beauty of Andaman padauk when used in decorative furniture work, I had never before realised how beautiful it could be until I saw the work at Messrs. Francis Peek & Co.'s building in Eastcheap. This work was carried out by Messrs. Holland & Hannen & Cubitt's, and the head of their joinery shops deserves no small measure of praise for its success. Apart from the inherent brilliancy of the wood, a new feature appears to be noticeable here. This is that the padauk seems to be endued with a living fire, which flashes and dulls with the alternations of light and shade. This quality is strikingly noticeable even in the daylight, but by artificial light it is much enhanced.

The padauk of Burma is of a duller colour but nevertheless it is a rich and beautiful wood, and it also possesses strength, toughness and elasticity to a marked degree.

FIG. 5.—Pyinkado, Lower Burma.

Both this wood and the Andaman padauk have been approved by the Admiralty as a substitute for sabicu for the particular purpose for which this West Indian wood is used in the construction of battleships.

INDIAN BOXWOOD.

I propose here to treat of a wood which, but for one point, would come in a different place in this catalogue. This is a wood which we have named Indian boxwood, for though it is not a true boxwood, it yet greatly resembles it in appearance and

growth. Similarly, the West Indian boxwood, one of the most useful in commerce, does not belong to the genus *Buxus*.

Now, one of the ever-present troubles which confronts the user of boxwood has been its great tendency to split, either when stored in the log or when manufactured. A shipment of this Indian boxwood, which was sent over to us before the Exhibition of 1920, has since been found to contain two different kinds of wood. One of these apparently does not split in the log or when cut up, or after manufacture,

while the other is liable to do so under all these conditions.

I have here two sections shewing the different behaviour of these two kinds. I have also a croquet mallet made from the non-splitting kind, which in all other respects as well as is as good as any that could be made.

By all those who are aware of this difficulty, which true boxwood so often presents, the great value of Indian boxwood will be immediately recognised.

HALDU.

When riding through the jungle near Bawbin in Burma, we suddenly came on a gigantic haldu tree towering up in a small clearing, and I was able to take a photograph. I measured the tree, which had a clear stem of over 80 feet free from any branch, and the buttressed butt-end measured 19 feet in length with a girth of about 17 feet, which is 5 feet 8 inches in diameter. The perfect log, cylindrical up to the first branch, measured 49 feet by 11 feet 2 inches or about 3 feet 6 inches in diameter. The top section, branched but straight, measured 55 feet by about 7 feet 6 inches in girth. There were also sundry other branches.

Apart from the beautiful colour of this wood, which is of a gamboge shade, somewhat resembling satinwood, it is interesting for the remarkable quality of the grain. Unlike the majority of woods, it is possible to work it in any direction with the greatest facility and without splitting. It is a splendid chair wood—the copy of a Hepplewhite chair which I have had made in haldū is perfect—while the colour is most artistic and agreeable. There are other special kinds of work for which this wood is exceptionally fitted, and amongst them I might mention particularly, brush work and all kinds of carving. Its peculiar smoothness and evenness of grain make it suitable for many other uses. It has been used to some little extent in India for shuttles and bobbins, though its great suitability for wood-work of a more valuable character will, I hope, prevent such a use as this in the future.

Koko.

An incident which happened recently will serve to shew you what a strange want of appreciation is sometimes shewn by those who use timber. I went to a building owned by a large wood-working concern

in London, and I found that the entrance doors, both outer and inner, were made of Andaman koko, which looked very well, though not in very good condition, and which, in my opinion, surpassed in general appearance any kind of walnut, including Italian walnut, which might have been used instead. Recognising the wood, I asked the proprietor, who has had great experience, of what the door was made, and he said, "Italian walnut." I found that he had purchased the timber more than 15 years ago under this description. Had I gone to him, or to any one else in a similar position, and suggested that koko should be used on its merits, I should have met with a more or less politely expressed refusal.

This timber is remarkable for its handsome colouring and strong figure; its standing qualities are excellent.

PYINMA.

Another of the magnificent timbers swept into obscurity under the baffling title of "jungle woods," and consequently almost entirely overlooked, is pyinma. It is probably a more valuable wood in its general qualities than any timber in the whole of the continent of North America, for example. In India, of course, it does not possess the same value as teak, as although it is partially proof against white ant, it is not wholly so. For Europe, I doubt whether its excellent qualities do not place it in almost as high a category as teak.

I have here some instrument cases made of pyinma. I think you will agree with me that they have as good an appearance as the black walnut or teak which is generally used, and I can assure you that in my opinion they will prove to be equally good, if not better, in wear. The first is a telephone magneto box, which demonstrates the suitability of the wood for corner locking. The next, a battery box with machine dove tail, shews the sharp and clean cut edges which can be obtained, and the third example, a bell push, illustrates the good turning qualities of the wood.

Its great reliability, coupled with excellent qualities of texture and grain, places it very high for decorative wood-work.

WHITE BOMBWE.

Another important wood is white bombwe, which is very strong and has a firm, hard and close texture. It should prove to be

FIG. 6.—Wardrobe in Indian Black Walnut

exceedingly serviceable here, though in India there is scarcely any demand for it. Here I want to say again that it is wrong to assume that, because an Indian wood is not used in India it cannot be used in this country. The chief factor which determines the use of a wood in India is its resistance to white ants, dry rot or other forms of decay. The prominence of teak in this resistance, coupled with its general availability, results in this timber practically holding the field against all others.

WHITE MAHOGANY.

Another of the cheaper woods is Indian white mahogany, a timber which a friend of mine recently described as one of the most useful of all woods for any kind of indoor work. It has a smooth, 'silky' surface and is very easily worked; it is light in weight but is strong enough for any but constructional purposes. It is in every way a suitable wood for all fittings and fixtures in cabinet-making, joinery and ship-building.

Of the other woods of which there are specimen panels here for you to see, there is unfortunately no time to speak at length, though I might commend to your notice

the coral-wood of the Andaman Islands, a reddish-golden, highly-figured wood which was known in France 70 years ago under the name, 'bois de corail'; sissou, which has been successfully used for fine cabinet work; thitka, which resembles Cuba mahogany; and a beautifully figured 'curl' of Indian prima-vera. There is also a panel of teak in what is known as 'fiddle-back' marking.

I suppose that I may be held to have been unduly enthusiastic on this subject, of which to-night I have but touched the fringe. If so, I must beg you to excuse me on the score of the deep interest I take in the matter and of the firmness of my belief that if the work is properly managed these timbers have a very great future before them in the markets of the world.

[The Society is indebted to Messrs. Macmillan & Co., Limited, for the loan of two of the illustrations (Figs. 2 and 5)]

Mr. HANNAY, after reading the paper, said he had taken the liberty of adding a few words on his own account. The last time he visited that lecture room, which was built, he believed, for the Society by the Brothers Adam, it struck him what a splendid opportunity

was afforded by the lower portion of the walls for panelling in fine wood. It would harmonise with and add to the rich effect of the paintings above, and of the fine ceiling. Robert Adam was an innovator and a ready acceptor of all new things that seemed to him good, and Thomas Chippendale before him, and of his time, was the same. He was satisfied that if those Indian woods had been introduced a century and a half or more ago, the best of them would have been eagerly taken up by those great men. Mr. Percy Macquoid, in his great work on furniture, had classed English wood-working periods as the age of oak, the age of walnut, the age of mahogany, and the age of satinwood, and they were now inaugurating a new period, the age of Indian woods. He suggested, with diffidence, and with hope, that that learned Society might fittingly join in and encourage the progressive movement by decorating the walls of its Hall in the manner suggested. The spirit of Robert Adam pervaded that place and neighbourhood, and he was certain that it would look on with approval.

SIR GEORGE HART then exhibited a large number of lantern slides descriptive of the paper, and explained them to the audience.

DISCUSSION.

THE CHAIRMAN (Sir William Meyer), in opening the discussion, said it had been a very interesting and practical paper by one who was a complete master of his subject. They would all, he thought, concur in Mr. Howard's view that a proper forest policy should combine scientific treatment of the forests in such matters, for instance, as planting, conservation and felling, with commercial acumen in disposing of the products. Before he left India, it had been recognised that the Forest Department needed development on the commercial side, and, as Mr. Howard had told them, that proposition was emphasised by the Industries Commission. It was no disparagement to the admirable Forest Service to recognise that some of its officers, absorbed in the conservation of forests, were not fully alive to the necessity for finding advantageous markets for the products, and thereafter it would be necessary to lay greater stress on that side of the Department's activity. He did not think either that many of those who had had Indian experience would contest Mr. Howard's dictum that as the forests in India, now a magnificent asset, had been developed by Government enterprise and under Government control, that policy, the success of which had been fully demonstrated by actual results, should continue. But when it came to the disposal of the products, especially in distant countries, private enterprise could be advantageously utilised, and Mr. Howard's own

activities afforded the best proof of that. He was sure that no direct Government agency could have done anything approaching what Mr. Howard had in the way of finding markets at home for Indian timbers, and the furniture and other objects that could be made from them. Mr. Howard had been constantly on the look out for such development, and the list he had given of the public bodies and companies who had been persuaded to utilise Indian timbers for railway carriages, panelling, flooring, furnishing, and so forth, evidenced his success. He believed that, as time went on and the virtues of Indian timbers became more fully recognised, there would be great developments in that direction; indeed, Mr. Hannay had already suggested one with which the Royal Society of Arts was greatly concerned, namely, that the fine Adam Room in which the meeting was being held should be panelled with Indian woods. Provincial Governments in India were now much more fully concerned with forest policy than they were prior to the political reforms lately introduced, and in the development of the industrial side of forestry full sympathy might be expected from Indian politicians, who had long emphasised the necessity for developing India's industrial resources. Old Indian as he was, the Empire Timber Exhibition, over which he had the pleasure of being escorted by Mr. Howard, was a revelation to him of the uses to which a number of their timbers, which as Mr. Howard had told them were not much esteemed or utilisable in India itself, could be put to here, and of the beautiful furniture, for example, that he had made therefrom. Before concluding, he desired to read a letter that had been received from an eminent Anglo-Indian (old style), Sir Louis Dane. Writing from Lyndhurst, he said:—

"I much regret that engagements here will prevent my being present at the lecture on the Timbers of India and Burma on 27th January. If the question of exploitation of the forests is to be debated I trust that the present urgent necessity for limiting the strength of Government establishments, and the very unfortunate results of former attempts to work the forests by direct Departmental Agency, will be remembered. In the Punjab and Kashmir the forests were practically unremunerative until they were developed by commercial agencies working under strict expert control." That was an interesting expression of opinion, though personally he shared Mr. Howard's views rather than those of Sir Louis Dane.

PROFESSOR R. S. TROUT, C.I.E., M.A., said that as the subject was being dealt with entirely from the commercial point of view he desired to mention that he was engaged for a good many years in trying to push Indian timbers both in India and in Burma. He then found the very greatest difficulty in getting private enterprise

to take up any new form of exploitation. Well known timbers like teak, sal, deodar and others were exploited to the utmost extent, and people were making such a lot of money out of them that it was almost hopeless to get any one to risk capital in trying to develop timbers which personally he knew were valuable, but which it took more convincing than his powers of persuasion were able to exercise to induce private enterprise to take up. He thought it was a wise move on the part of Government when they found an agent in this country who was in a position to push some of those lesser known timbers and to make such a very good business of it. Any one who went to the Timber Exhibition in London must have been impressed, whether he knew anything about Indian timbers or not, with the extraordinarily fine use to which the timbers were put for panelling, furniture, parquet flooring, etc. It was necessary, however, that a note of warning should be given in connection with one question dealing with the export of new timbers, namely, that there was sometimes a tendency to float quantities of timber on the market before the market was ready to absorb them. There was also a risk of large quantities of timbers which had made a name, as some of the Indian timbers were already doing, being put on the market by all and sundry without possibly a full appreciation of even the identity of the timber, and of other timbers possibly something like them, but not identically the same, being used. He knew of cases where harm had already been done in that way not only in India but elsewhere. The author had mentioned in his paper that the forest area of India was 250,000 square miles. That statement required a little qualification, because that area included an area of 141,000 square miles of what were termed unclassified forest, i.e., forests which had not been brought under systematic treatment. A considerable area of those unclassified forests would in time either be cleared for cultivation or abandoned as not worth working. The point was a minor one because the forest area of India, including Burma, was so vast that, even after meeting all their own requirements, India, Burma and the Andaman Islands were in a position to export a large quantity of timber.

SIR CHARLES H. ARMSTRONG said he was an enthusiast with regard to the future of Indian timbers in this country. While he was not an expert on the Indian timber question, he had always been a great believer in Burma teak, and he knew as a fact that many of the woods which were produced in India were very suitable for decorative purposes and also for railway work in this country. He was glad to hear the Chairman say that his offices were to be decorated with Indian woods, and he felt sure the High Commissioner could be trusted to advertise them to the best of his ability. When he came

home in 1914, after 30 years' residence in India, he brought with him all his furniture which had been made in Bombay of the very best Burma teak, and he would be very pleased to show it to any of the Fellows of the Society who cared to call upon him at Guildford. Nearly everybody who came into the house admired his furniture and asked him where he obtained it. Teak took a beautiful polish, and in his opinion it was one of the most satisfactory woods for furniture making. It might be a little heavy, but at the same time it was very substantial. With regard to the question of the cost of bringing woods from India and Burma to this country, there was no doubt that the expense of bringing some of them down to the seaboard was very considerable, and he imagined that would take away a great deal of the profit. Once, however, they had been brought to the sea, the freight ought not to be any great deterrent. He did not believe that the freight and shipping charges from India would be very much greater than on the so-called mahoganies, walnut woods and oaks which were imported. The people of this country were very conservative, and it was very difficult to induce them to use woods other than those to which they had always been accustomed, but he felt sure that, if Indian woods were only properly advertised, in the course of time the demand for them would grow. But it had to be recognised that it was a very difficult trade for private enterprise to take up. He entirely agreed with Professor Troup that too much of any one timber of a new quality should not be put on the market at once. The best plan to adopt was to put small quantities on the market to be sold at prices which the market could afford, and gradually to force the market up to a paying level. That might possibly take years, but when once the trade had been established he was certain it would continue satisfactorily.

SIR GEORGE S. HART, K.B.E., C.I.E., said it was stated in the paper that an appreciation of the needs and difficulties of the industrial world must guide the trend of scientific research. None of them would be so stupid as to deny the truth of that assertion for a moment. The point he wished to urge was that, with regard to the science of forestry, industry must not expect too much. The forester had to think in half-centuries, and his work was planned for the benefit of posterity. He could not for an instant swerve from the paramount necessity of maintaining his forests in such a condition that their output would be assured in perpetuity, and, in so far as that might be possible, increased steadily. America, Canada, and, he believed, Australia also, had had practical experience of the grave results which must follow if that policy was not enforced. India as a whole, he was thankful to say, had had no such experience, for the Forest Service, though

only some 65 years old, was established in time to prevent any general destruction of the forests. For that reason he regarded the future for Indian timbers as particularly hopeful; and he thought they could be certain that as long as British influence on Indian policy was maintained the upkeep of India's vast and valuable forest estate might be regarded as assured. Given reasonable facilities for exploitation, the question was not, therefore, whether the supply of Indian timbers could be maintained, but whether markets to absorb the supply could be found. The author had expressed himself in favour of exploitation by Government Agency as compared with private enterprise; at any rate, with regard to the work to be done in introducing little known timbers to the markets of the world. That was, perhaps, rather a controversial question, and one naturally desired to avoid controversy as much as possible: also he had spent many of the earlier years of his service dealing, among other things, with departmental timber work in all its aspects: the actual exploitation, the transport from the hills to the plains and the business end in the timber depots, so that he might, perhaps, be somewhat prejudiced in favour of the system he knew so well. On the other hand, he had seen many instances of forest work under private enterprise from one end of India to the other, and, speaking generally, and from the point of view of the forest officer only, he did not like it. Obviously it was the system to work on under certain conditions; i.e., where the conditions of extraction and transport were easy, where markets were fairly close at hand and assured, and where the trees to be removed could be marked and sold annually under strict regulation, notably with regard to the completion of the removal from particular areas. But where extraction and transport were difficult, markets not assured, and long term contracts with easy conditions with regard to the payment of royalties, the execution of the various works and the clearing of the areas, had to be offered in order to induce purchasers to come forward; then he knew that in the interests of the forests, private enterprise should only be called in, in India, and he included Burma, where for some reason or other departmental work was impossible. It was to be noted that he referred only to the regular forest work, that was to say, to the exploitation and transport of the produce to timber depots in the principal markets, or even to the nearest main line of rail, coupled with such preliminary conversion as might be necessary. Once that was completed and the felling areas cleared so that regeneration operations could be taken in hand at the proper time, private enterprise for the final conversion and marketing of the produce should be brought in: but it should be brought in on terms which would yield a fair return to both parties and not leave Government

with the very low share which it had so often received in the past. He did not wish any one to infer that he thought the big timber trading firms in India and Burma had deliberately treated Government badly. They had not, and had he been running a timber firm, or working for one, under the agreements they were fortunate enough to receive from Government, he would have done exactly as they had. Their business was to make as much for their shareholders as they could, subject to complying with the terms of their contracts, and naturally they did nothing beyond the terms unless they thought it advisable in order to keep Government in a good temper and ensure the renewal of their leases. They could not be expected to spend money on making a really good road which might be useful in working another area later on, possibly by one of their competitors, when a rough track would serve their purpose; or, again, to go to extra expense in order to clear a forest before they needed to do so. If not clearing it meant a lot of damage to young growth, or much extra expense and work on regeneration, so much the worse for the forest officers whose job it was to attend to those things. One of the objections often urged against departmental working was that it prevented the forest officers from attending to their silviculture. To a considerable extent that was true in the days before the war; but that reproach was now removed, as the Forest Service now had a branch of forest engineers, specially trained in up-to-date means of exploitation and transport, which would take over all work of that kind and leave the regular forest officers free to attend to their legitimate duties. In his opinion, the Governments of India and Burma had reason to be very grateful to the author for the work he had done in connection with Indian timbers. Without that work few of the timbers mentioned in the paper would have been heard of in England to-day. Reference was made in the paper to the work in Indian timbers carried out in Messrs. Francis Peek and Co.'s building in Eastcheap. He was taken to see that building a few days ago, and he really did not think that he had ever seen more delightful timber work. In particular, the laurel wood and gurjun panelling in the Board room and the door of that room, laurel wood on the inside and padauk on the outside, were strikingly beautiful and showed what could be done with those woods under skilled supervision.

MR. J. W. KITCHIN, O.B.E., said the chief impression left on his mind by the paper was the vast asset that India possessed in her timber, and it was quite clear that the country appreciated that fact because she had a splendid body of forestry officers to look after it. It means could be adopted of prolonging the life of timber, the object of the author, who had written his paper from a commercial and

practical point of view, would, he thought, be furthered. The trees of India, apparently, could be divided into two divisions, the first containing valuable and durable trees, which were known and sought after, and the second containing inferior trees, but among which there might be valuable trees also. There were 37,000 miles of railway in India, and the Railway Departments apparently were the biggest consumers of timber in the country, drawing their supply principally from the first division. If something could be done to enable those consumers to utilise timbers of the second division treated in such a way that it lasted longer than would naturally be the case the object desired by the author would be attained, namely, the wood would be used to the best advantage of the country. He greatly admired the way in which the economic side of the question had been dealt with at Dehra Dun, where for ten years past the subject of how best to treat timber in order to prolong its life had been under consideration. Coal tar, creosote products, insecticides and so forth had been tried, and a recommendation had been made that Powellizing should be extensively tried in India, in the same way that it had in Australia. If that recommendation was adopted India would benefit, the idea being to utilise some of the timbers of the inferior class. As an example of what had been done, 800 or 900 "chir" sleepers which had undergone the Powellizing process were laid down in a place where ordinarily the untreated timber lasted two years. After six years only one of the sleepers had been attacked by white ants, and less than six sleepers had to be rejected, so that the extension of the life of the timber was three-fold. The same sleepers seen again nine years after they were put down, or four-and-a-half times the life of the untreated timber, showed 70 per cent. of them still in place, 30 per cent. having to be rejected. The question of the antiseptic treatment of timber seemed to him a very important one for the economic success of India, because if it was possible to conserve Indian timber and use in the country, by means of the process referred to, timber which it was difficult to use at present, the more valuable and better timber would be set free for export to the world. The Powellizing process produced in less than a day what Nature took many years to produce, and by its adoption timbers of India imported into this country in a green state could be converted into high-class furniture within a few weeks of the time they were landed at the docks.

MR. E. M. HUGHMAN said that, as a large purchaser of Burma teak in India, he had been much struck with the figures given of the value of imports into England of Indian and Burma wood. Those figures showed that 94 per cent. was Burma teak and only 6 per cent. of Indian

wood. Practically the only wood that could be used in India for ship-building, furniture, and domestic purposes was the best Burma teak. The decorative wood of India was very good for export, but of very little use in India itself. Personally he would rather see 94 per cent. of Indian wood imported into England, which would leave India free to make use of the Burma teak wood. He was perfectly certain that India and Burma could absorb all the teak wood that could be produced, and it would also keep the prices at a more reasonable figure. During the war very great difficulty was experienced in obtaining Burma teak for building wooden vessels; the price rose from about 40 rupees to 220 rupees a ton, and the difficulties of getting teak from Burma to Bombay and Calcutta were very great owing to shortage of shipping. Speaking as one engaged in trade in India, and from the point of view of the benefit of the people there, he thought it would be very much better to develop the beautiful woods of India which could be used very much better for English purposes, and leave Burma teak wood to those in India who required it so much.

MR. F. H. FRANCE said he wished to speak on behalf of the class that had hitherto not been represented in the discussion, namely, private enterprise, which was still the villain of the piece. The Forest Department, which had done excellent work for a long time and was looked upon as the hero of the piece, had thought commerce was one of the things it ought to leave alone before the author appeared upon the scene. Professor Troup and Sir George Hart had stated that private enterprise had not shown itself sufficiently active in the matter of introducing Indian woods which were undoubtedly of great value. His reply to that was, what had the Government done? Personally, he knew Burma fairly well, but he did not know of any single forest in Burma in connection with which the Government expended a single rupee on junglewood extraction; the whole business was done by private enterprise. When Government desired timber to be extracted from the forests they gave out licences or leases, including lately leases to the Burmese. Of course, every nation had the right to work its own possessions, but he thought time would show that the Burmese could not work an organisation on the same scale as the big firms. As the Government had done nothing in the way of extracting timbers from the forests by Government enterprise, it naturally fell to the private firms to do so, but what were the inducements at present? There were no markets; the markets were in course of creation; but it was up to the Government to show that private enterprise was at fault in the sense that it had not done anything. Private enterprise in one particular case with which he was acquainted

had taken up a lease of forests containing jungle woods and was prepared to put down £100,000 for making the railways and building the mills on the spot. He desired to use the argument, what would some people think if the Forestry Department said that it was prepared to spend £100,000 on a small area of 50 square miles? He ventured to say it would take a very great deal of consideration indeed; in fact, it would have to go on being debated years and years before anything was done. If the Government were prepared to come forward and put down £100,000 to work an area of 50 square miles, then he would begin to believe that the Government had real faith in junglewoods, but until they did so he could not but hold a different opinion. The Government were quite prepared to work the very pick of the teak forests in Burma for which there was a market, but when it came to the other forests they wanted somebody else to pick the chestnuts out of the fire for them. All trades had their slumps, and at the present moment the teak trade was probably at the bottom. Nevertheless, the Government were simply throwing thousands of tons of teak on to the market irrespective of the consequences. Was that an inducement to a private firm to spend £100,000 to work a new proposition? Personally, it did not seem to him the way to encourage private enterprise to take risks in other markets. The Forest Department was an excellent body of men who knew their work thoroughly, and who had done and always would do very useful work in conservation, but when it came to utilisation he was not at all sure that all that had been said about private enterprise could be justified. Anyhow, if the Government really thought that they could work better than private enterprise they now had the opportunity of showing what they could do in the case of the Indian jungle woods. Much had been heard of their value, and it only remained for the Government to act.

COLONEL SIR CHARLES E. YATE, Bt., C.S.I., C.M.G., M.P., proposed a vote of thanks to Mr. Howard for his valuable paper, to Mr. Hannay for reading it, and to Sir George Hart for describing the illustrations. He also, on behalf of the Indian Committee, thanked Sir William Meyer for taking the chair. Sir Charles Yate said he hoped it would be realised in England that woods for which there might be a considerable demand in the home markets were, as Mr. Howard had said, in small demand in India. In that way England ought to be able to obtain these woods at a price below their intrinsic value, which would be advantageous to the buyer in England, and thus help to their ready sale. He was glad to hear the statement in the paper that the author had been able, when in India, to lay the foundations of a scheme whereby it would be possible to have direct

shipment of timber from Indian and Burmese ports to England. The Indian Forest Service was now a very fine one indeed. That Service previously received its training in France or Germany, but it now trained its own men in India and in Burma. He hoped a good and efficient Forestry Service would be properly developed throughout the Dominions, the Crown Colonies and also in Great Britain, as it was essential that forestry should be taken up as a practical question in all portions of the Empire. It was only, however, by the help of Government initiation and exploitation that Indian woods could be brought into use in England, and he sincerely hoped that something more would be obtained from the Government of India than what the Chairman had described as full sympathy. Work was required by the Government of India to start the industry and to develop the trade between India and England, and he was sure everyone present looked to the High Commissioner to establish that trade on a firm and substantial basis.

THE CHAIRMAN said that he would do his best.

MR. W. COLDSTREAM seconded the motion, which was carried unanimously.

MR. W. COLDSTREAM, late I.C.S., writes:—

In seconding the vote of thanks, it was too late for me to make any remarks, and as requested, I now write the few words I wished to say. It would have been a decided advantage, both to the public and to experts if the scientific (Latin) names had been given in the case of each species of tree named. I may say that confusion may well arise with reference to some, for instance, boxwood, which was mentioned. The wood, which the Forest Department has named Indian boxwood, is said not to be of the genus *buxus*; but there is a very fine wood which is called boxwood in the north of India (shamshad or chikni), which has been identified as *Burus sempervirens* (Stewart's "Punjab Plants"). The tun was mentioned—a very valuable wood, but our Punjabi shisham, or tali *Dalbergia sissoo*, did not hold one of the places of honour, which I humbly think it should have done, as it is such a very valuable wood. Both the shisham and the tun are splendid for furniture, and (the shisham especially) for many other economic purposes. Sir Charles Armstrong gave us a kind invitation to view his furniture of Indian woods. I should be very glad to show my specimens of furniture made of shisham and Punjab walnut and small articles of boxwood and ebony to any who are interested. Of course, the paper could include but a small fraction of the vast subject, and the names of but a few woods could be given; but besides those above mentioned the various species of *Eucalyptus* have become so im-

portant in India that it would be interesting to hear something about them, and what species of this genus produce woods which promise to be really useful as timber. Their rate of growth is enormous. I hope I may be excused for venturing these remarks. I am much interested in the subject, for I saw the Forest Department formed in North India under Lord Canning, and the first Lord Elgin, and was present at the first (as I believe) Forest Conference in Simla in 1875, at which I had the honour of reading a paper on district arboriculture; and as a frequent wanderer in the magnificent forests of the Simla district (which were beautifully illustrated and described by Sir George Hart) and a quondam resident in the beautiful forest hut at Nachar, which we saw on the screen, I should like to mention the names of Cleghorn, Brandis, and Stewart, who first described this vast and valuable forest area in the early sixties. As hard-working pioneers of the Department, and its earliest administrators in North India, I would like to record their names here. It is earnestly to be hoped that the Diarchy will deal wisely and cautiously with the vast property of the Indian Forests, and with the Department of able men who have been selected as its officers. I very heartily associate myself with the proposal to give private enterprise the utmost scope consistent with the safety of the forests. Great destruction was wrought in the Forests of the Simla district in earlier years before proper conservancy was introduced.

The practical issue of the paper was well voiced in the speech of Sir Charles Yate, and we would all join very earnestly in encouraging the action of the High Commissioner in carrying forward the exploitation of India's useful woods, and for their speedy introduction to the markets of Europe and America.

MR. G. M. RYAN, F.L.S., late Indian Forest Service, writes:—

Apropos of what was said by Mr. Howard in his valuable paper in advocacy of Government agency as the best means of exploitation of the forests under the Government of India, it may not be uninteresting to record that as far back as 1890-1893 this question of private *versus* departmental enterprise came up for consideration in connection with the working of the forests in Sind, a province included within the limits of the Bombay Presidency and about the size of England and Wales, containing approximately 1,200 square miles of forest. The question was decided in favour of the former method, *i.e.*, private enterprise, and adopted, with results which the experience of time (over 25 years) has demonstrated to be a great improvement over the latter method. The subject is too long to be discussed here; suffice it to say that as I initiated this change of system into Sind, I trust it will not be con-

sidered presumption on my part if it is asserted that there appear to be certain parts of India where a similar alteration in forest policy could probably be inaugurated with advantage not only to the Forest Department and timber merchants, but to the State generally. In Sind for example, the change in policy, which my successor in office continued and extended with marked ability all over the Province, effected an almost immediate annual saving to Government of about three lakhs of rupees, without in the least degree impairing efficiency. In a report submitted to the Secretary of State for India in 1920 on the high commercial and politico-economic importance of the forests of Sind, this fact was emphasised and the suggestion was thrown out that private agency under the circumstances, in regard to forest exploitation might be introduced or given a trial, at any rate, in certain localities in India where it did not exist. One speaker at the meeting (Mr. J. W. Kitchin) advocated the Powellizing of some of the Indian timbers. This is a question which also was discussed many years ago (in 1905-06) in the Bombay Presidency, and Sir Henry Procter, (C.B.E., with commendable foresight and enterprise, formed a syndicate in India to treat Indian and imported timbers in this way. He has spent over £25,000, as far as is understood, in his efforts to get Powellized wood of certain Indian and other woods accepted, especially for railway sleepers, but so far apparently not with much success, although the Forest Economist at Dehra Dun (Mr. Pearson) has reported fully and very favourably on the method of Powellization. All this shows what private agency can do and is prepared to do in India.

MR. F. J. WAKING, C.M.G., M.Inst.C.E., writes:—

I consider this to be a most interesting and valuable paper, but it might be rendered even more valuable if the author could give the botanical names of the timbers he specially mentions. I had the privilege of visiting the Empire Exhibition of Timber in 1920, and was struck with the beauty of many of the cabinet woods there shewn, and am glad to learn from the particulars given in the paper that, largely I suppose owing to the publicity afforded by that Exhibition, practical use has been made of many of these woods. During 1920, a year certainly of inflated prices, wood and timber to the value of £82,145,214 was imported into the United Kingdom the whole of which, except timber to the value of £12,495,610 from Canada and teak to the value of £1,406,550 from India, came from foreign countries. The author confines himself principally to cabinet timbers, but others are worthy of attention. In view of the fact that the consumption of timber by the world is largely in excess of its natural

production, the question of timber supply in the future is a problem the gravity of which cannot be exaggerated, and demands the most serious attention. It is possible that some of the Indian and Burmese woods mentioned by the author might be grown in other tropical portions of the Empire. It is also perhaps possible that some varieties of the Eucalyptus, especially the Jarrah (*E. marginata*) and Karri (*E. diversicolor*) Western Australian timbers, of much value for railway sleepers and general construction work, might find a suitable habitat in the drier parts of India, such as Sind, the Punjab and Central India, or in parts of South Africa.

The Blue Gum (*E. globulus*), another Australian timber, is quick growing and readily adapts itself to the far different climate of the hilly districts of Ceylon, where the rainfall in contrast with that of Australia is heavy and where at altitudes of from 3,000 to 6,000 feet above sea level it grows well without special care, and it is perhaps possible that the Jarrah and Karri might possess equal adaptability to difference of climate. It would be interesting to know whether this experiment has been tried.

NOTES ON BOOKS.

ENGINEERING STEELS. An exposition of the Properties of Steel, for Engineers and Users. By Leslie Aitchison. London: Macdonald and Evans. 1921. 25s. net.

The extent of the practical service which Mr. Aitchison's book may render to the Engineer will be at once evident to anyone turning over the pages, which in all amount to XXXII + 396, but 47 inset plates at the end of the book are included in the paging to bring all of the figures conveniently within the scope of the index.

Characteristic properties of steel as bearing on its suitability for the manifold purposes to which it is now applied are set forth in the clearest manner, while the various methods by which the many types of industrial steel are produced are touched upon lightly, yet sufficiently; this being what the Engineer or user requires in selecting qualities suitable for specific purposes.

Thus it will be understood Mr. Aitchison's book is a work of details, many being minute and at first seem almost trivial in importance; they are not so, however, in fact; as a fine adaptation of quality of steel to use was one of the leading technical issues in the great war, the present work is largely a peace issue of the war.

A work consisting mainly of minute detail requires the utmost care and skill in arrangement, classification, and indexing, and Mr.

Aitchison is to be complimented on the success with which he has overcome the many difficulties incidental to good arrangement. He makes it quite clear that he regards adaptation or conformity between quality and use of steel as a leading matter in progress and he says "the steel of the watchmaker's drill is of no use for the rails of a locomotive track, neither is the steel of the rifle barrel good for drilling armour."

The concise chapters, treating of productive methods and the stages of progress, trace modern differentiations in quality to the pioneer work of Huntsman in 1742. Huntsman was a watchmaker, who then adopted the method of fusion in order to produce homogeneous steel for springs. Valuable as the crucible method may be for experimenting and for preparing extra fine steels for special uses, it gives place to the electric furnace, Bessemer converters and open hearth methods for production on a large scale.

Large-scale working, however, despite its many economies and advantages has special defects and troubles which are more or less inherent to the larger scale of work. The large ingots in cooling develop varieties of crystallisation in the different parts (p. 26), and the forging or working of the ingots distorts not only the individual crystal but also the groups. Although it may be thought that the crystals can by forging lose their identity and perfectly merge into each other, this is not always the case, perhaps by reason of an outer skin of non-metallic impurity around the crystals. In this way, and otherwise, we often have a lack of homogeneous structure as shown in many diagrams (Figs. 14, 17, and others). The sectional photograph, Fig. 101, and the text p. 295, show us how many latent dangers may become active under special conditions of working; cracks arising in the sharp angles of a castellated shaft, as shewn.

All the essentials relating to the workshop qualities of steels are treated of in a remarkably thorough and satisfactory manner

OILS, FATS, AND FUELS. By Thomas Hull. London: Blackie and Son, Ltd. 1921. 3s. 6d. net.

This miniature handbook (144 small octavo pages) is according to the preface, intended for the use of Students in day and evening continuation schools.

Although calculated to awaken interest in the subjects treated of, and to lead the student to larger works, there is rather a lack of such exactness in chemical details as appear desirable in an educational book, and as an example we may refer to p. 5 and p. 70, where the relationship of glycerine to the fatty acids is considered but with neglect of the water factor which is involved in this relation. On each of the pages mentioned above is a statement, in the form of an equation, which involves neglect

of the water factor: hence incorrect, but possibly considered good enough for a pupil in a primary school, who may learn more in after stages. A brief mention of the Wilson method (or Tilghman method) of hydrolysing fat with superheated steam would have made a correct understanding of the matter easy; moreover, this method was for about half-a-century (1854 to 1904) approximately the leading or perhaps only, method by which pure glycerine (Price's) was manufactured. A concise account, but complete in essentials, of this remarkable process will be found on p. 274 of Part III., Miller's Elements of Chemistry, 1862, edition.

It would be grossly unfair to close our review at this point, as the notable merits of the book far outweigh any omissions or faults which may be discoverable. The style is lucid, the order, sequence and system are good and to a casual reader the interest is likely to be maintained. In short, a copy may constitute a remarkably useful present to a schoolboy, as leading to interest in subjects otherwise outside his usual range of thought.

The following may be mentioned. Illustrations in text showing laboratory device for determining melting points, the digester for rendering fats, the hydraulic oil-press, the laboratory fat extractor by solvent, the coco nut in aspect and section with its thick outer covering of roire, map of Scottish oil fields followed by a diagrammatic section of the shale-retort now in use, a charcoal meller in section with turf covering, a modern coke oven, oil furnace for steam boiler and a modern spray burner or atomizer with double air stream.

Inset plates show the forest gathering of turpentine, oil wells at Los Angeles, stills for petroleum, oil reservoirs and barge, oil tanker at sea, Port Sunlight 60-ton soap pan with accessories, and a Tyneside plant for condensing coke oven products.

BLUE PRINTING AND MODERN PLAN-COPYING.

By B. J. Hall, M.I.Mech.E. London: Sir Isaac Pitman and Sons, Ltd. 1921. 6s. net.

Here we have a text book of photographic contact printing and kindred modes of reproduction as far as such work is incidental to office routine, or to the routine of industrial establishments, as for example engineering works where plan-copying at high speed is often an important feature.

The book drifts outside the strict range of contact printing, where this is desirable, and treats of the use of a special set camera for reproducing office matter.

Details are given mainly with respect to appliances for rapid and convenient work, and it is generally assumed that the requisite sensitive materials as also chemical preparations will be purchased ready for use, as far as this is practicable; hence Mr. Hall's book is not to

be regarded as a treatise on the photographic methods in their inner chemical aspects. Further there is no concealment as to the fact that Messrs. B. J. Hall and Co., supply appliances and materials; their advertisement being prominent at the end of the book.

In its scope as defined, the book is thorough and satisfactory and it embodies many hints as to miscellaneous matters, as for example the making of type-written sheets which will serve as originals in photographic printing.

RELATIVITY, THE ELECTRON THEORY AND GRAVITATION. By E. Cunningham. London: Longmans, Green and Co. 1921. 10s. 6d. net.

Professor Cunningham presents to his readers a sequent and lucid account of Einstein's concepts as to relativity, and mentions a slight but important, change in usage as to terms (p. 2 and 8), by which Einstein's "principle of relativity" is now more precisely termed "the special principle of relativity," and it is based on the view that physical experiments will not serve for determining the absolute velocity of a body through space.

We may perhaps be allowed to preface our notice by some partially applicable parallels. Let us suppose a person standing at the end of a platform when an express train passes at full speed, with the whistle sounding.

Although the speed of the train in relation to our bystander may be regarded as uniform, and the note of the whistle will be uniform to the engine driver, our bystander on the platform may notice a change from a higher to a lower pitch or note at the instant that the sounding whistle passes in front of him; the approach of the train increases the frequency with which the waves of sound reach our observer, and the contrary effect (diminished frequency) gives him a sense of a lower note the instant that the whistle has passed. An intensified form of this apparent or relative change in pitch may be noticed by a person in a train which meets another train of which the whistle is sounding.

In a similar way light coming from a source travelling towards a position is made higher in pitch as far as this position is concerned, and *vice versa* (Doppler effect); a fact which enables us to estimate the speed at which certain stars are moving in relation to the earth, the datum for observation and measurement being, for example, the shift of the F line in the spectrum.

The above-mentioned instance in its two forms (as to sound and as to light) is an example of the many cases in which a phenomenon may vary considerably according to the relation of the observer to the source.

We may put the case otherwise and far more generally by saying that the physical manifestations of the ens, are subject to, or implicated in the predicaments (categories); ten by the count of Aristotle, or four (with qualifications)

by Kant's system; but relation has place in both lists.

As bearings on datum-places in intellectual progress let us now take three periods of astronomical study and result. About 200 years before Christ, Eratosthenes, who had charge of the Library at Alexandria, having evidently learned what was then the modern view of the heavenly motions, made measurements with the best instruments at his disposal. These were only divided to arcs of one-sixth of a degree; but notwithstanding this his measurements confirmed the conjectures of Hipparchus and others as to the obliquity of the ecliptic, though his observations were disturbed as he made no correction for the greater refraction of light at the winter solstice. Eratosthenes also made measurements as to the circumference of the earth and although the geometry of his method was correct there were disturbing factors, and some data were not exact.

During the long interval from Eratosthenes to Newton, methods and knowledge advanced much, so Newton was able, in his *Principia*, to promulgate such incontrovertible data as to the relation of gravitation to orbital movement, that the fundamentals, as touching the question of Galileo's "heresy", were settled for ever. We must not, however, forget that Newton laid one of the foundations on which the next great step was to be laid, as without modern developments of Newton's studies as to fluxions that notable stage in progress to which we are being led by Einstein and his followers could not be developed.

At the outset Professor Cunningham makes it evident that the purely metaphysical aspect as to the infinities (space and time) is put aside or is outside the question. "Physical Theory has nothing to do with absolute space" he says definitely (p. 2), but the space with which physical theory deals is "one aspect of the relations which have been observed between the phenomena with which physical theory is concerned."

There may be many aspects of such relations, and each aspect may be in relation to one particular status of reference; the status of reference first suggesting itself for light being the ether. For the present purpose one must not regard the ether as an attenuated form of matter, but as a medium which can penetrate matter and be undisturbed by the passage of matter through it. This concept of the ether, as being stagnant, led to endeavours to trace such physical effects as might, in theory, be expected by the motion of bodies through it: but with no very definite success, doubt being alternately directed towards the experiments and the finer borderings of the stagnancy concept. Great difficulties arise, and as all astronomical and gravitational data are involved in observations by rays of light, there is not only the question of any gravitational bending

but also the question of the Doppler effect, already mentioned in our introductory notes, and further treated of by Professor Cunningham (p. 42).

In studies of this nature the effects due to space and time become so interwoven that Minkowski has been led to the view that space and time are two aspects of a single reality (pp. 6, 72, 75) and in developing this idea he pictures a four-dimensional status in which space and time become space-time; a fourth dimension, or structure-element.

Arago's contention of 1818 that if glass moves towards the light the relative velocity of the light at entering must be greater than if the glass is at rest, is considered at some length, with conjectures as to why Arago did not realise the experimental confirmation which he expected; and also the culmination in Fizeau's experiment as to the effect of a stream of water on light. The recent aspects of Fizeau's experiment are figured and described in relation to the special principle of relativity, and there is a profound study of Weyl's theory of electricity and the electric theory of matter, also the deflection of light in a gravitational field, now confirmed by observations of the perihelion of mercury and in less degree by the work in relation to the recent solar eclipse.

Professor Cunningham is to be congratulated at the satisfactory way in which he carries out his intention of producing a book which shall be of service to the general reader and the experimental physicist.

GENERAL NOTE.

GIANT GRASSES FOR PAPER MAKING.—Hitherto tropical and sub-tropical countries have relied mainly for their supplies of paper-making materials on the forests of the northern temperate regions. Wood pulp, prepared from spruce and other timbers in the United States, Canada and Scandinavia is, for example, imported into India and Australia for the manufacture of the cheaper kinds of paper, whilst countries, such as those of tropical Africa, in which manufacturing industries are in a less advanced state, import practically all their paper ready-made. In almost all these countries, however, there are native products which could be used for making paper, and in some cases a survey of the materials available is being undertaken. Bamboos appear to be the most promising source of paper-pulp in India and the Far East, whilst in other countries large grasses, many of which are similar to bamboos in appearance, exist over extensive areas and could be used for the same purpose. In the current number of the Bulletin of the Imperial Institute, a comprehensive account is given of these giant grasses. Preliminary trials have proved that many of them give a satisfactory yield

of pulp, which produces good paper. In the case of the so-called elephant grass of eastern tropical Africa, these results have been confirmed by large-scale trials and the material has been used in Uganda for Government printing paper, which is of excellent quality. Such grasses, owing to their bulk, could not be exported to Europe at a profit, but it is suggested that they might be employed locally for paper making or for conversion into pulp for export.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, FEBRUARY 20. Health, People's League of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Dr. R. S. Rows, "Association of Ideas, Recognition and Memory."
Geographical Society, 131, New Bond Street, W., 8.30 p.m. Mr. A. F. R. Wollaston, "Natural History of South-Western Tibet."
Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Mr. W. Dale, "Christianity in Roman Britain."
British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. A. J. Davis, "The Internal Decoration of Ocean Liners."
East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Mr. A. T. Arnall, "Hydro-Electric Power in India."
Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal meeting). Discussion on "The Emergency Use of Oil Fuel during the Recent Coal Strike." (Liverpool Centre)
The University, Liverpool, 7 p.m. Dr. S. S. Richardson, "An Oscillograph Investigation of the Gulstad Relay."
TUESDAY, FEBRUARY 21. Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m.
Royal Institution, Albemarle Street, W., 8 p.m. Sir Arthur Keith, "Anthropology of the British Empire." (Lecture I.)
Anglo-French Society, Scala House, Tottenham Street, W., 6.15 p.m. M. M. Thiery, "La Comédie de Moeurs et le théâtre d'Alexandre Dumas, fils."
Marine Engineers, 85, The Minories, E., 6.30 p.m. Mr. D. R. Hutchison, "Types of Large Marine Oil Engines."
University of London, at the Imperial College, Royal School of Mines, South Kensington, S.W., 5.30 p.m. Colonel N. T. Belalew, "The Crystallisation of Metals." (Lecture I.)
At the London School of Economics, Houghton Street, Aldwych, W.C., 6 p.m. Sir Joseph Stamp, "The Administrative Factor in Government." (Lecture II.)
Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.
Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C. Meeting in commemoration of the first meeting of the Society of Telegraph Engineers in 1872. To be continued in Wednesday and Thursday. (North-Western Section), 17, Albert Square, Manchester, 7 p.m. Messrs. Haden and Whyall, "The Utilization of Waste Heat from Electrical Generating Stations."
Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Colonel T. C. Hodson, "The Primitive Culture of India." (Lecture V.)
Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. G. A. Booth, "Natural History Photography."
Automobile Engineers, Institution of, at the Chamber of Commerce, New Street, Birmingham, 7 p.m. Dr. Ormandy and Mr. E. C. Craven, "The Physical Properties of Motor Fuels—a Discussion in their bearing on the Motor Industry."
Educational Needlecraft Association, Essex Hall, Strand, W.C., 7.30 p.m. Mrs. L. Glasier Foster, "The Importance of the School Sewing Lesson."

WEDNESDAY, FEBRUARY 22. Massage and Medical Gymnastics, Society of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Dr. Gladstone, "The Structure and Functions of Muscle."
University of London, at the London School of Medicine for Women, Hunter Street, W.C., 5 p.m. Dr. H. H. Dale, "Some Recent Developments in Pharmacology." (Lecture I.)
Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. (1) Dr. C. W. Andrews, "Description of a New Plesiosaur from the Wealden Clay of Sussex." (2) Mr. T. Landell-Mills, "The Carboniferous Rocks of the Deer Lake District of Newfoundland." With Notes on the Petrography by Dr. A. Gilligan, D.S. and on the Palaeontology by Dr. A. S. Woodward.
Literature, Royal Society of, 2 Bloomsbury Square, W.C., 5 p.m.
Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Mr. C. O. Blagden, "Matriarchy in the Malay Peninsula."
Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Mr. P. C. Varner-Jones, "Industrial Colonies and Village Settlements for the Consumptive."
Industrial League Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. R. Horniman, "A Proposed Solution to the Transport Problem."
Electrical Engineers, Institution of (South-Midland Section), The University, Birmingham, 7 p.m. Mr. F. P. Whitaker, "Rotary Converters, with Special Reference to Railway Electrification."

£41,810 7

The above list includes all subscriptions received up to February 17th. Further lists will be published in the *Journal* from time to time.

Fellows of the Society are reminded that the amount aimed at by the Council is £50,000, which will enable them to renovate and decorate the house and make it attractive and convenient for Fellows.

*The first list was published in the *Journal* of December 2nd, 1921, and the second in the *Journal* of January 13th, 1922

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 27th, at 8 p.m. (Cantor Lecture.) ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington, "The Mechanical Design of Scientific Instruments." (Lecture II.)

WEDNESDAY, MARCH 1st, at 8 p.m. (Ordinary Meeting.) EMANUEL MOOR, "The Duplex-Coupler Pianoforte." PERCY A. SCHOLES, Music Critic to the *Observer*, in the Chair. (Demonstrations of the Instrument will be given by the Author, Miss Winifred Christie and Mr. Max Pirani.)

TWELFTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 15th, 1922; SIR HENRY NEWBOLT, C.H., D.Litt., LL.D., Chairman of the Departmental Committee on the Teaching of English, in the Chair.

The following candidate was proposed for election as a Fellow of the Society :—
Armstrong, Frederick William, Manchester.

The following candidates were balloted for and duly elected Fellows of the Society:—

Forrest, L. R. W., London.

Gomat, C. S. Ganapathier, Madras, India.

Soames, Mrs. Geraldine, Rugby.

A paper on "The Necessity for Speech Training, and the Need of a National Conservatoire" was read by MR. CLOUDESLEY BRERETON, M.A., L.És.L.

The paper and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURE.

On Monday evening, February 20th, PROFESSOR ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., delivered the first lecture of his course on "The Mechanical Design of Scientific Instruments."

The lectures will be published in the *Journal* during the summer recess.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and copies can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

TENTH ORDINARY MEETING

WEDNESDAY, FEBRUARY 1ST, 1922.

SIR CECIL HARCOURT SMITH, C.V.O., LL.D.,
Director of the Victoria and Albert Museum,
in the Chair.

THE CHAIRMAN said that probably most of those present knew Mr. Wilcock already, first of all as a director for some time of an important firm of cotton printers and also as a man who had for many years been a designer in the allied art of wall-paper designing and as a man who had considerable interest in the particular trade with which the paper would deal, and particularly owing to the fact that he had had for many years a studio in his offices in Bedford Square which had served more or less as a school of design for a large number of people in the trade. He felt sure that, as Mr. Wilcock was a distributor, a designer and also a practiser generally of the two kinds of design, that for cotton and that for wall-papers, the paper would be one of extraordinary interest.

The paper read was :—

SURFACE PRINTING BY ROLLERS IN THE COTTON INDUSTRY.

A COMPARISON WITH OTHER PROCESSES OF PRINTING PATTERN FOR CRETONNE, DRESS MATERIAL AND WALLPAPER.

By ARTHUR WILCOCK,

Special Inspector of Textile Design, Board of Education.

INTRODUCTION.

GENERAL EDUCATION.

In all recent conferences and discussions on the advancement of industrial art and the improvement of public taste in the selection of what is produced, it has in the end been unanimously resolved that the public should be educated to discriminate between the meretricious and ugly and the fit and beautiful. The child must from the beginning be taught to know the reason why this thing is good and the other bad, as in morals so in the domain of art which has a direct bearing on morality and culture. *Beauty*, to which is allied fitness for purpose in all common objects made by man for the use of man, must come into the child's school curriculum. A child is taught to draw and paint but not to discriminate or select. We who are interested in better production realize that for such a millenium to be consummated another generation will have to appear, and that the next best thing to do is to educate the "man behind the counter." The man, coming immediately in contact with the buying public should know, at least, something about the goods he is selling and the process by which they are made.

He should also, if this is not expecting too much, be able to appreciate good design and beauty of production. When the customer approaches with an open mind he should be able to talk intelligently on his goods and transmit his enthusiasm. Enthusiasm and sincerity are the dynamic forces of business. This is quite a different thing from an offensive didacticism or an assumed intelligence. An assumed intelligence can have no enthusiasm; it is too much on its guard for an attack on its more vulnerable parts. So eventually we shall come to discredit that false and pernicious business axiom that the man who can tell the most untruths procures the best results.

These are days of specialization, and surely it must be of benefit to anyone

connected with a particular branch of trade, one who is handling every day of his life some particular production, to know and understand the processes of that production. I should consider such a one ordinarily intelligent and possessed with a desire to get on in his business.

Knowledge is power in the factory, the warehouse and the shop. It can gain and retain the confidence of a customer, it can build up a big business, it can make a great empire.

I often hear it contended that the customer does not want to know about process or design or the reason why one thing is more expensive than another, or why the expensive thing is so on account of its hand production and beauty of design and workmanship.

Limited and careful hand production at the workshop by the craftsman and unlimited production by the machine at the factory should be appreciated by the salesman, for if he mistake one for the other, which is not unlikely if he is ignorant of process, he will defraud and disappoint his customer. This is not good business.

Many things of this nature must be taken into account in intelligent and good salesmanship.

From my own personal experience as a customer in a shop and from remarks I have overheard by other customers, I deny most emphatically such a statement as that the average person does not want to know all about what he is buying. He does want information and assurance from intelligent salesmen, and he resents attention from a "dud" or a child who can tell him nothing about the goods but the price.

I have greater confidence in the public, and to say they do not want to know about the goods they are purchasing is a slight on my fellow citizens.

It gives one cause for great satisfaction to feel there is a great educational movement in progress among the best houses of business.

In the production of *artistic* goods it is beginning to be realized that someone who knows a little about art and design is necessary and important for the merchandising of these goods. The artist himself, provided he is not one of those with his "head in the clouds," is being sought out. Extraordinary developments are at hand in business in the search for personality in effective representation.

You all have heard the old Persian proverb—

"He that knows not and knows not that he knows not is a fool—Shun him.

He that knows not and knows that he knows not is simple—Teach him.

He that knows and knows that he knows is wise—Follow him."

The whole tendency of trade now is for better education all round from top to bottom, and those members of it who are in constant contact with the public must know more, must think more and must express themselves better.

Although artistic production has advanced, it has yet much to achieve if only a higher standard of education obtains.

It is, therefore, to distributors in particular I would address myself, although if what I have to say may enlighten the designer so much the better, because for him to appreciate the possibilities and limitations of a process is an absolute necessity. The designer and artist is one always striving after new effects of ornamentation, new interpretations. It is for him to give effects that are possible by a process, but which hitherto have not been tried; to set the craftsman who follows him, whether engraver or "putter on" a difficult task; something that shall tax his ingenuity to the utmost rather than something the craftsman has done time after time before. A designer worthy of the name is one so familiar with process that he can carry it to its utmost limit of expression, always working up, never down to a dead level of the merely mechanical.

In this particular it is essential also that the producer in contact with the artist should be able to perceive artistic effects possible of achievement. Many novelties of great commercial value have been seized by a producer's keen perception of artistic effect and its possible reproduction in his process. The producer, for instance, who dismisses an artist's rough and unfinished sketch because he can only understand a mechanically finished working drawing misses many an opportunity of procuring a good thing for his business.

We will all agree then that all have much to learn and that education and more education is wanted in every department of industry and commerce. Indeed, it is now recognised as of great national importance if we are to keep our place in the world.

I shall, therefore, make no further apology for giving a paper the subject of which concerns one of our biggest national industries.

PROCESS.

The various processes used to impress cloth with a pattern in more or less permanent dye colours are many. Some of these have gone out of use in our time for various reasons. I will name them first.

1. *Hand painted*.—The *entirely hand painted*, obviously on account of its laboriousness and its co-relative cost in labour.
2. The *hand-filled*.
3. The *Batik*.
4. The *Madder style*, vat printed.
5. The *copper plate*. Replaced by the rotary plate or *copper roller*.
6. The *Perrotine*.
7. The *Stencil*.
8. The *copper roller*.
9. The *surface roller*.
10. The *hand-block*.

So that at the present moment what remain to us and have been proved under present conditions to be sound economic propositions are the three last processes which I will try to demonstrate.

The *surface roller* recently re-introduced for cotton printing, but in universal use for wall paper, for many years past.

The *copper roller* introduced as far back as 1783 by Thos. Bell.

(It is possible to combine these two in one machine.)

The *hand block*, almost as old as history and still "going strong," although at the present moment somewhat under a cloud and discredited by reason of its failure to meet the enormous recent demand. (The hand printer, through fear of unemployment, will only take a very restricted number of apprentices.)

SURFACE PRINTING.

May I venture to suggest how it came about that this surface printing of cottons was re-introduced? Some of you will remember a certain vogue of having the curtains and draperies of a room to match the wall paper. A certain eminent French manufacturer and factor of wall paper quite naturally thought the same rollers might with advantage be used for both. Simple designs rarely exceeding six colours were

then in fashion. Once, however, having got the process well in hand and its many difficulties overcome, experimenting in more elaborate designs of many more colours was the sequence. This enterprising man of genius has reaped his reward in finding his goods in great demand. Genius is defined as the infinite capacity for taking pains. If one adds to this a high appreciation of design and artistic quality, you have in this Frenchman a successful art producer, compelling the attention of the whole trade by the beauty and artistic quality of his goods. He has, moreover, the satisfaction of now regarding a belated emulation on the part of some English manufacturers.

It is a process that has been in use for many years for the printing of wall papers. The more ordinary method of printing cottons and textiles by machine has been that of the copper roller, the pattern being engraved into its polished surface intaglio fashion.

Surface-print is a word used in contradistinction to this by reason of the pattern being raised above the roller.

This roller is of wood, and copper ribbon is driven in edgewise as a border to the forms which are filled in with felt. The copper ribbon stands by itself where mere lines are required in the design.

This felt has a greedy affinity for colour and will take up more than it can discharge on the cloth to be printed, some of it remaining absorbed in the felt. This is a demerit, and makes the washing and cleaning for other colour samplings a troublesome business. This dye colour heavily charged with 'paste' or gum as its vehicle also gets embedded into the interstices between the felted figuration of the design.

It is an uncleanly process compared to the copper roller which is so very easily cleansed, and is the chief reason it has been left so severely alone by the English printer for these many years.

Undoubtedly the process really serves better the purpose of the wall paper printer who uses colours which are more readily removed. Less difficulty would have to be met if no variety or change of colour was needed in a cotton pattern to be submitted to the trade, but this is contrary to usage, and many samplings showing many different colourings have to be made. A thorough washing of the roller must be effected each time or a following impression would be contaminated or dulled.

The surface of the roller presented to the cloth so nearly resembles the surface of the hand block that one would be disposed on this account to call it the "rotary block" process. Its qualities as compared with the copper roller print are in its softness of outline and general colour tone; also the tendency of the colour to what printers call "bleed" and run, giving these prints a more liquid aspect than in those textiles printed by the ordinary copper engraved roller. The finished print is very nearly the same as the hand block print and I can well appreciate its being mistaken by the trade. Many instances of this have come under my own personal notice.

HOW TO DISTINGUISH THE SURFACE PRINT FROM THE HAND BLOCK PRINT.

1. The first distinguishing feature is its narrow width; nothing yet has been produced over 30 inches. However, a 50 in. cloth may yet come from this process.
2. The register repeat spots on the margin or selvage.
3. No superposition of colours as in the Block print. Each colour must impress the plain cloth and each is edged by a darker shade of its own by reason of the profuse colour discharge on the cloth.
4. A general tendency to a lower colour tone, especially in the French product, which is usually printed on grey unbleached cloth of loose texture.
5. The "mealy" quality in half-tones of the deeper colours due to paste resist. (See Half Tones.)
6. Light blotches, or grounds, showing no joining lines as in Block work. In this one particular the machine surface process has an advantage over the hand-made print.
7. A certain streaky effect on the reverse of the print.

The rate of production as compared with hand process is a very different economic proposition—two-and-a-half to three miles a day as against twelve yards. This will make the latter hand process the only process for those firms that require rare specialities, for an exclusive trade.

The slow and necessarily costly hand block work must for ever hold its own as a

special product by reason of its restricted output. It can never be made common by an enormous production such as is possible with a rotary process of printing. Speeding-up in any artistic process must inevitably lower its artistic and intrinsic value. In fact the rotary machine is a serious problem in industry by its over-production resulting in forced sales, while on the other hand, limited production gives the block a certain precious quality which alone commands respect apart from its greater permanence and artistic quality.

In like manner, if such a simile may be allowed, the precious diamond is only kept precious by restricting its supply from the mines: its value lies not only in its beauty but in its rarity. However beautiful pattern design may be, its beauty soon fades if seen in every other house and shop window.

Before proceeding further to describe this particular surface process of printing textiles we will for a moment consider the copper roller process and its real possibilities. You all know that on the surface of a bright and smooth copper roller the very finest of lines can be expressed by the graver or by an acid corrosive. Also that it is possible to get an effect equal to the finest mezzotint by the hand punch following the stipple or half etch. Such fine qualities of engraving have, however, of late years not been required. To imitate rather the breadth and largeness of the block print has been the demand of the trade. It is a matter of opinion whether such productions are a legitimate expression of the process; it may be conceded that the results obtained by this and the surface process are more decorative and less pictorial, therefore more suited to textile ornamentation. But this finer quality of the copper roller has been abused in the past and made to reproduce quite realistic effects which are in the true sense of the word undecorative. Natural flowers very beautifully rendered in all their delicacy equal to the finest mezzotint in softness of shading and gradation of tint are all very good for a framed picture but when repeated over a large surface become tiresome and are not decoration. We have yet to see these same qualities of soft gradation put to a better and more soundly artistic use. In this respect the copper roller process has not come into its own by its abuse, on the one hand reproducing heavy block effects, and on the other by reproducing light and frivolous effects; abuse by under expression,

and abuse by undecorative bad design aiming at mere realism.

It is a thoroughly sound process of impressing cloth with pattern in many ways excelling the surface process, but the prints do not possess those liquid effects which we get from both the surface and hand block print.

The finishing of the cloth in this copper process has yet to be improved; a certain stiffness is generally present which compares unfavourably with the soft draping quality of the surface print.

Here, however, may I add a word of warning to the printer of surface goods? This artistic draping quality has been due to putting the design on to cloth with little substance. It has been disappointing as a covering material for furniture on account of its flimsy texture. We cannot have it both ways, however, and seeing it is sold loosely draped and not stretched over furniture, for which purpose it is mostly used, one cannot be surprised at its popularity as a saleable article.

The secret of successful printing is suiting the process to the cloth on which it is going. Naturally, a rough, uneven-textured cloth is suitable for broad decorative design and an even-textured cloth for finely engraved designs. Linen with its inequality of texture has been found eminently suitable for "surface" as well as "hand block." Cotton cloth usually is too even and mechanically correct, but if in the spinning of the yarn we would arrive at the uneven qualities of the linen cloth, I am sure the surface printer would be made happy with a texture that suited his process admirably.

DEMONSTRATION.

Now let us proceed to demonstrate the "surface" process.

THE "PUTTER ON."

Our first and most important step is putting the artist's sketch on to the rollers. Each colour will have to be defined and transferred on to its separate roller—a process requiring great judgment and skill and also much experience. Allowances have to be made for *fine* fitting of the parts or sometimes a *full* fitting. In fact the "putter on" can mar the whole production of a factory if he is not something of an artist and cannot follow sympathetically the artist's original sketch.

All the rollers cut to receive their

several colours can now be set up in the machine. In its rotation each roller must be very accurately registered to impress the cloth in its allotted place.

IMPRESS.

This is the contact of a colour-charged roller or block and the textile—the impressing of the already woven texture of a cloth with a dye. The pressure can be too light or too heavy. In the printing of a wall paper we have a pressure which is mere contact because the paper has no texture and the colour is nothing but pigment laid to dry on the paper's surface. In the printing of cretonne, however, some considerable pressure has to be used to feed a more or less "hungry" cloth—a term used by the hand craftsman—which has to be dried, steamed and washed and dried again before it is finished.

The contact pressure in the copper engraved roller process is tremendous. The cloth has so to speak to suck the colour out of the roller's most delicately engraved part: even those parts of the roller more deeply engraved carry but very little colour compared with the surface roller or block.

COLOUR.

All the colours used now with very few exceptions are aniline dyes. There are several groups or families of these, all of which have their different qualities.

They are:—

Acid, Basic, Direct, Mordant,
Spirit, Sulphide, Union, Vat.

Unfortunately, some of the more brilliant of these are fugitive, and while brilliant colour in pattern is required by the public it is the duty of the salesman to inform his customers of such fugitive qualities. One would be disposed to think it in the best interests of the print trade if manufacturers would desist from using any colour that has a bad reputation in this respect. It must be disappointing to the customer especially in times such as we are now going through, when economy is urgent, to discover a colour fading after a week's exposure to light; or after cleaning, however carefully, to find a flat and dead looking print with all its original brightness gone for ever.

Much of this colour non-resistance to light and cleaning depends on the failure of the colour to lay perfect hold of the cloth in printing.

I am quite sure the shopkeeper who carries heavy stocks of prints will appreciate these

remarks. I can imagine some considerable part of their time must be taken up in dealing with customer's complaints of fugitive colours. How much they would welcome for their own credit the advent of more reliable colours! We have yet to discover a gamut of colours all of which would remain fairly steadfast to light and true to their original after washing. My experience goes to show me that in this respect greater reliability is to be found in the copper-impressed pattern which is due to greater pressure allowing the colour to become thoroughly absorbed in the fibre of the cloth.

HALF TONES.

In many colour processes half tones are produced by a less deep incision in the plate or roller carrying the full tone. This is the case in the copper roller process used in cotton printing.

The half tone is called the "stipple" or, by the engraver, the "half-etch." This naturally carries less colour to discharge on the cloth than the full etch.

In the block process no such effects can be given and when a lighter tone is required another block must be supplied by the block cutter.

In surface printing, however, half tones can be given to the full tone by a very simple device. To illustrate this, I will give you, by way of diversion, a little experiment. Here is a sheet of white cartridge paper, on which I will, with clear water in my brush, draw three broad lines. Before this is dry, I will wash over the entire sheet with a green shade of colour. You will now see that the three broad lines that I put in with clear water appear in a lighter half tone. The reason is obvious. The dry sheet of paper takes the full tone and the previously damped portion of it takes only the half tone.

Apply this principle to a printing machine with its various coloured rollers set up round the "bowl." The first roller to come into contact with the cloth carries no colour at all, but merely water or "paste" and impresses this on to all parts of the design where half tones are intended. This "paste" roller must, of course, have cut on its surface parts which impress the cloth on some or all of the other colour rollers. So you will see the great service this one roller performs in producing half

tones of any or all of its followers in their quick succession.

I have spoken of the old hand craftsman referring to a cloth as "hungry" when it absorbs much of his colour. This water or paste roller on the surface cotton printing machine, may be considered as having half appeased this "hunger." This method of producing half tones is not well suited to the darker colours in a pattern. The results in these cases are inclined to give a "mealy" or sooty effect—a very sure sign of differentiation from the hand block process where no mechanical half tone effects are possible.

The introduction of this "water" or half tone roller into a surface printing machine with twelve rollers, will result in giving the design all the appearance of being printed with double that number of colours. When, therefore, buyers are splitting hairs and farthings over price and manufacturing costs, they will be out in their reckoning, if in counting up the number of colours, they do not remember this wonderful but simple, device for producing half tones.

PREPARATION AND FINISHING OF CLOTH.

In describing to you the general process of preparing the cloth for printing and the after process of steaming and washing, I shall give you no more information than what you will find in the numerous technical text books on the art, but a cursory glance at the apparatus as used in some works (as you know, every works has its own tried formula) will give you sufficient idea of what the process is like. A few lantern slides will also help to illustrate what little I have to say on this very important part of the process, but which I have felt unnecessary for my purpose.

If what I have said and the views I have expressed have the effect of procuring fair play for the little hand craft of block printing I shall have achieved something. The surface roller can never produce as good a thing as the hand block, and the fact that the trade in their ignorance have sometimes passed this off as such on the public is sufficient excuse in itself, if any is needed, for my having brought you here this evening. A surface roller printed textile is a travesty of the hand craft which by its more careful and laborious process gives to the public a more lasting and beautiful production. As I

have before said, speeding up production where artistic quality is concerned is always done at a sacrifice, not only of durability in this case, but of richness and solidarity of effect. The machine by its enormous productive powers can supply the multitude and is a sound commercial proposition. If at the same time it is wisely controlled and can disseminate really beautiful patterns it is doing a good and necessary thing in the world; but when the machine-made article injures the reputation of hand-work then all right-thinking people will condemn it, and in the long run it is bad business.

CONCLUSION.

Processes of manufacture, I repeat, can be abused and perverted. I have tried to show you how much more refined the copper engraved print might be if it were true to its process and did not attempt to imitate a process which is characterised by broad massiveness, and I have also tried to show you that, through no fault of its own, the surface roller print is near akin to the hand-block process print but much inferior in permanency by reason of its more rapid and superficial process, and that the public may be made to pay dearly for what as members of an economic community they have a right, and a just right, to expect at a much more moderate price.

It is an easy matter to make a fortune by putting on the market a machine-made article which to all appearances is the same as a necessarily costly hand made article. Such kinds of trades do not rank high in a nation's credit. It is the production of the article which is what it appears to be, downright sterling in its quality. Such goods have built up British credit—goods excellent enough to attract all the world as buyers, and *satisfied* buyers who will come again for more.

DISCUSSION.

THE CHAIRMAN (Sir Cecil Harcourt Smith, C.V.O., LL.D.), in opening the discussion, said that in the Victoria and Albert Museum there were examples of Indian printing dating back to the sixth century A.D., to the Coptic tombs of Egypt, through the various wonders of the Orient, the Batik printings from Java and the magnificent cotton printings from Ispahan in Persia, down to the interesting results obtained in the Jouy factories, of which the author had shown some specimens in the slides he had exhibited that evening. In the Loan

Court of the Museum there was an extremely interesting series of illustrations—made, he thought, for Mr. G. P. Baker's book, to which the author had referred—showing the processes of cotton printing as used in India, those illustrations being placed side by side with the splendid collection of early cotton prints from India which were lent to the Museum by Mr. G. P. Baker. One point to which he wished to direct attention was the particular quality of cotton printing as being originally an imitative process, and in that way it was subject to disadvantages as well as to advantages. He thought it would be a great pity if cotton printing developed too largely in the direction of direct imitation of the various varieties of subjects which a copper engraving could deal with. The tendency could be detected to some extent in the cotton printing of the eighteenth century, where it began to tend towards the reproduction of pictures. Personally he thought there was no particular disadvantage in the register not being too exact in cotton printing: the material did not lend itself, nor demand the same sharpness and clearness of design as is necessary in wall-paper. There was something in the particular nature of a textile which made softness a quality to be definitely aimed at. He thought the kind of design the author had shown in which he had introduced birds, the naturalistic form of design, which had been so popular, was in itself a step in the right direction. It was necessary, however, to avoid going too far in the direction of naturalism: if one did that one would be neglecting the primary laws of textile design. Another point to which he wished to draw attention was the author's remarks about the education of the manufacturers, the designer, the distributor and the public. The authorities of the Victoria and Albert Museum were largely out for that education, but it presented enormous difficulties. If one went to the manufacturer and said, "Why do not you produce something more artistic?" the reply was, "Show me how it would pay and I will produce it:" whilst if the designer was asked, "Why do not you design something more artistic?" he replied, "Show me the manufacturer who will invest his capital in it and I will design it." Until the four elements—the manufacturer, the designer, the distributor and the public—could be brought together and something produced which would be a commercial success and worth investing capital in, he did not see how the ideal would ever be attained. It was that ideal which he hoped would some day be achieved, partly through the help of the Victoria and Albert Museum. It was with that object in view that at the present time there was an Exhibition arranged by the British Institute of Industrial Art, the primary object of which was to bring the manufacturers, the designers and the buying public together to see what

could be done. The exhibits were placed side by side with the great works of the past, not with a view to having the great works of the past copied by modern productions but rather in order that the designers might be inspired by the fine traditions of the past. This country should have an English tradition in every art and in every commercial product, and that could only be obtained by the study of the great productions of the past. He agreed with the author that there were many hopeful signs at the present time. In spite of the fact that the conditions of labour, the conditions of research and the conditions of many other matters were extremely difficult, there was a distinct movement forward which was most encouraging.

MR. A. F. KENDRICK (Department of Textiles, Victoria and Albert Museum) said he would like to offer his thanks to the author for a most interesting paper on a subject which intimately concerned the British public, both as users and as people who had benefited by the great industry that had grown up in this country. The author had dealt particularly with the latest process of cotton printing, the roller process, and it almost seemed as though there was nothing further to be invented in that direction. Perhaps it was a fact that the last stage in the mechanical development of impressing patterns on cotton had very nearly been reached. It was rather interesting to compare the latest process with the earlier ones. It was hardly admissible to trace back the beginnings to the East, because neither cotton nor the Oriental methods were known when the process began in this country; we had to look for the origin to our remote ancestors who used the primitive brush and pot of woad dye. That was when cotton printing began; the only thing that was not there was the cotton. In the West, the printing of books, stuffs and wall-papers, began somewhere about the fourteenth century. Those three things were very intimately associated. Just about the time that people, turning from the manuscript, learned to print books, they began to print on stuffs instead of painting them; and as far as wall-papers were concerned their patterns were very often the same as those for stuffs, which was just as well, seeing that they had to be placed near one another in the house. The next stage might be taken as the seventeenth century, when the oriental hand-painted stuffs came into this country and brought about a great revolution. They had an ancestry going back many centuries. Then one might go on from that time to the middle of the eighteenth century, when the roller came in. He noticed that the author called it the "roller," but years ago another word was used for it a good deal, i.e., the "mangle," which was perhaps a little more descriptive. By passing the stuff through the

mangle and repeating the same design without a break English cotton printers were, as the author said, able to produce three miles of stuff in a day instead of twelve yards. With regard to the question of education in matters of art there were so many to educate that one did not know where to begin. He thought, however, that the people really most in need were the general public. The members of the general public were a little afraid of being educated, because there was an old saying about a little education being a dangerous thing. He did not believe that was true. He believed that a little imperfect or a little misunderstood education was very dangerous indeed, but if people obtained only a general outline of the processes connected with the design and manufacture of the things of daily life it was a step in the right direction. The people of this country had as many opportunities of seeing great works of art of the past as had the people in any other country in the world, and if they had their eyes trained by looking at those things and obtained a little insight, such as the author had been giving that evening, into the methods of production, it would enable them to distinguish between good things and the showy things which deceived so many people, and part of the present trouble would be overcome. The manufacturer, the designer and the distributor would still have to be dealt with, but he thought they would all fall into line when once the public took the reins into its own hands and learned to understand to some extent what the processes were and obtained an elementary idea of the difference between what was good and what was bad.

MR. W. H. D. KING expressed the pleasure he had felt at listening to the author's most interesting paper, and also desired to compliment him on the large audience present at the meeting and the great interest that had been manifested in block printing. Speaking as the head of a factory employing one hundred hands on block printing, he could say that block printers had always had a good friend in the author. Two points in the paper interested him very much as a block printer. One was that the artist who designed the pattern should not attempt by block printing a style of work that the process was incapable of performing satisfactorily. The author particularly emphasised that point. It must be very annoying for people to buy designs produced by an artist who had no knowledge of the craft and to find that those patterns were of no use for block work. The other point that had particularly struck him in the paper was that designs should be applicable to the cloth for which they were intended. The texture and weave of the cloth should be taken into account in the preparation of designs. Many patterns, as the author pointed out, were more suitable for linen or a rough cloth than for

a fine cloth. He did not think the distributors, who showed an increasing tendency to have their own patterns, sufficiently realised the benefit they would obtain by having particular designs on a particular make of cloth. The designers themselves should have a little more practical knowledge of the industry than they had at the present time. How they were going to obtain that knowledge he did not know. Their position was a very difficult one. They were continually asked to find something new, but there was a certain catholicity in the requirements of the public that the new did not suit, and consequently the old patterns were repeated one after the other. Some years ago he had had an opportunity of examining the old books of a print works established near Preston about the year 1798, and written against one pattern was:—"The French Belle." This is not a Canterbury-bell or a heather bell but the imaginary belle of an ingenious Frenchman from whom the no less ingenious Joseph Aumonier copied it—but so it bring money—no matter! That proved that in those days, more than a hundred years ago, they were still copying other people's designs. He wished again to thank the author for taking up the cudgels on behalf of block printing, and trusted that those members of the audience who disposed of printed goods would remember that block printing was the best process.

MR. R. H. CARTON, speaking as a distributor, said that distributors had very great faith in block printers, but he thought it would be an advantage if they would display a little more of the ingenuity that the French printer had put into a great deal of his surface printing. He did not think English block printers should be derided, because he believed they could do anything that was wanted. With regard to surface printing, a great deal of the effect seemed to be due to the fact that the surface printer printed on a natural or unbleached cloth, whereas the block printer was very fond of printing on a white cloth and thus produced a harder effect than the surface printer obtained. One reason why surface printing had such a great vogue was that it came in at a time when the spending power of the public was very limited. If the block printer would try to soften his colouring and to modify some of the very harsh effects that had been prevalent during the war and to produce simpler designs, he would have nothing to regret and would be able to hold his own against other processes.

MR. ROBERT PERCIVAL BAKER wished to say a few words in defence of the surface print. He would not say that the author condemned the surface print, but he felt that the author very much preferred the block print and rather criticised the permanency of the surface print. Personally he attributed that entirely to the fact

that the Frenchmen who had put on to the market about four-fifths of all the surface prints that were on the market at the present time had used the wrong type of colour; they were not using the very best colours they could get. He did not profess to have analysed those colours, but from what he knew himself of the complaints that had come from the retail trade he could say they were complaints due to bad colour having been used—cheap colour. That was the cause of the lack of permanency, and not any defect in the process of surface printing. The surface machine would furnish a thin light cloth just as well as any block printer would do it. The author did not appear to agree with that, but if some of the specimens of surface printing that were exhibited at the meeting were turned over to show the underneath side it would be found that they were furnished as well as the specimens of block printing, i.e., the colour had penetrated right through the fibres practically to the same extent as in the case of the block printed article, and the prints contained as much per cent. of colour chemically fixed into them. He did not see how it could be argued that the fugitiveness of colour in the surface print was due to some defect in the method by which the print was produced, as his experience was that a surface print could be furnished as well as a block print, if the process was carried out in the right way. In his opinion surface printing was a means of bringing into the homes of the great mass of the population of this country a really good article, well designed, well turned out and at a reasonable price, whereas the block print was not within the reach of the multitude.

MR. R. L. JARVIS, referring to the question raised by Mr. Baker as to the permanency of colours, asked if it was not a fact that the permanency of the colours was largely due to the way in which the prints were finished. If a surface print or a roller print was subject to a thorough steaming and a proper washing, would not the colours be nearly as permanent as they were in a block print?

MR. WILCOCK replied in the affirmative, and said it was the superficial after treatment, the washing, that was accountable for the stability of the colours. He quite agreed with Mr. Baker as to the educative power of good designs and good prints disseminated among the people at a moderate price. That was one of the educative advantages of the rapid production to which he had referred. Personally, however, he could not afford to buy cheap stuff; he could not afford to buy a thing that was going to last about half or one-third the time of a more expensive article. Whilst admitting the educative value of a machine turning off miles and miles of stuff of good design, it was necessary to take into consideration the fact that it might not be permanent and its fugitive

quality might render it more fit for a duster than anything else.

On the proposition of THE CHAIRMAN, a hearty vote of thanks was accorded to the author for his interesting and instructive paper, and the meeting terminated.

CORRESPONDENCE.

PANELLING THE HALL WITH INDIAN TIMBERS.

The suggestion put forward in the discussion following Mr. Alexander Howard's paper on Indian Timbers, that one or more of these should be used in panelling the hall at the Royal Society of Arts, appears to be an excellent one from two points of view.

First, such usage would serve as a practical lesson in, and a public example of, the preferential employment of timbers grown within the British Empire, and would further serve as a demonstration of the qualities of the Indian woods used and as an illustration of the wealth of valuable, yet more or less unfamiliar, decorative woods abounding in our Empire.

Secondly, as among Indian timbers there is so wide a range of colour and pattern, it is possible to select woods from India that provide schemes of decoration producing artistic effects varying from subdued or bright monochromes to brilliant variegation.

TRANSPORT FACILITIES IN THE BELGIAN CONGO.

In view of the extensive industrial development of the Belgian Congo during recent years, the need there for more adequate transportation facilities is becoming urgent. According to a report by the Secretary to the United States Trade Commissioner at Brussels, an expenditure of 700 million francs, allowing for the construction of new railways, having a total length of 2,380 miles, would open up vast sections of this territory suited to the growing of cotton and tropical products. The present means of transportation from these regions, the first stages

by native porters, and thence by small river boats which follow the windings of the shallow streams, renders the marketing of bulky products uneconomical.

The great waterway of the colony is the Congo River, furnishing with its branches 15,000 kilometres of navigable waterways and draining over a million square kilometres of land, or more than one half the Congo. Ocean liners of 8,000 tons can dock at Matadi, about 150 kilometres from the mouth of the Congo. From Matadi merchandise is transported by rail to Leopoldville, or rather Kinshasa, a few kilometres from Leopoldville and a more important industrial centre. From Kinshasa to Stanleyville, a distance of 1,700 kilometres, the river is navigable, having a minimum depth at low water of 1.40 metres. This permits the navigation of river steamers up to 1,000 tons, but except for one 600 ton steamer the largest units in service are of 500 tons.

By comparing the costs of river and rail transportation in the Congo, it is evident that construction of new railway systems will not reduce heavily the traffic now enjoyed by the water routes. Rather, it will open up new territories hitherto inaccessible. Railway rates before the war were four times those of transportation by water. During the war the railways increased their rates, thereby encouraging still more the transportation by the waterways.

The Sonatra, or Société Nationale de Transports Fluviaux, maintains boats on the Congo and Kasai rivers. This organization, which has taken over all the material and installations of the Government, was constituted as a semi-private enterprise, but up to the present the Government is the sole shareholder. In addition to the Sonatra, there are several private companies which in some cases provide transportation for the products of others. Prominent among these are Compagnie du Kasai, Compagnie des Chemins de Fer du Congo Supérieur aux Grands Lacs Africains, les Huilleries du Congo Belge, and Citas. The total tonnage of the boats operated by the Sonatra is approximately 30,000, or about equal to the combined tonnage owned by the private companies.

Judicious expenditure on harbour construction at strategic points along the Congo would reduce the costs of water traffic. At present Matadi has a dock 500 metres by 50 metres. Seven kilometres below Matadi the Government possesses 500 metres of river bank at Ango-Ango, where it is proposed to construct a port connected with Matadi by rail.

The poorly constructed railway from Matadi to Leopoldville is not in a condition to bear all the traffic from that district. At the date of the armistice the capacity of the system was only 80,000 tons. However, the extensive improvements which are being urged will allow a train hauling from 200 to 300 tons to cover the distance in less than twelve hours.

THE PEANUT INDUSTRY IN EGYPT.

Peanuts in Egypt are cultivated on sandy land which is not suitable for the cultivation of other crops. The crop is sown in May, which is considered the beginning of the peanut season. During the 1915-16 season a little over 11,000 acres were sown. The area was increased to over 13,000 the next season and was followed by a season of approximately 14,000 acres. In 1918-19 the area sown was almost 15,000 acres and in 1919-20 approximately the same area was under cultivation.

The yield varies greatly according to the locality, kind of nuts grown, and the attending soil and climatic condition. The average yield per acre is about 2,000 pounds. The average annual yield of nuts would, therefore, be about 30,000,000 pounds during the two latest years referred to, and although this is not a very large quantity, it is, nevertheless, very profitable to grow these nuts in Egypt, as the land used, being sandy, is not suitable for the cultivation of cotton or other valuable crops and the cost of growing the nuts is comparatively low. Under present labour conditions, writes the U.S. Consul at Alexandria, the growing of groundnuts on otherwise useless soils yields from 50 to 100 per cent. profit on the actual cost of cultivation and harvesting, but not allowing for the cost of the land.

There are three varieties of peanuts cultivated in Egypt. The Sudani, a small compact nut varying in colour of shell in accordance with the soil in which it is planted, but generally pale buff or grey brown, is cultivated to a greater extent than the other varieties and enters mainly into the export trade. The pods usually contain two nuts, rarely three or one. The variety which brings the highest price is the Hindi, introduced from southern India. These nuts are larger than the first variety and are mostly found with three kernels. The El-Huri, a nut of European origin, is a large two-celled nut, which is not grown so often in Egypt. Since peanuts have been introduced into Egypt from almost all parts of the world, the varieties have become so mixed that it is difficult to recognise them. The only variety which has clearly maintained its main characteristic is the Sudani. In October, 1920, the Sudani was valued at 32 Egyptian pounds (£E = £1 0s 6½d.) per metric ton on the Alexandria market. The Indian variety was valued at 38 Egyptian pounds per metric ton.

During 1918 and 1919 the exports of peanuts from Egypt amounted to over 2,380,000 pounds, and 5,700,000 pounds, valued at £E 38,890 and £E 111,115 respectively. Palestine was the heaviest purchaser, taking in 1918, 1,667,868 pounds, valued at £E 27,778, and in 1919, 3,044,322 pounds, valued at £E 60,165. Tripoli, in 1918, took 436,674 pounds, valued at £E 6,613, and in 1919, 958,335 pounds, valued at £E 16,521. Other countries participating in

the exports were Syria, Arabia, British Mediterranean possessions, Greece, Rhodes, the Sudan, and Turkey.

According to the figures given above, the average yield of peanuts in Egypt is about 30,000,000 pounds per annum. Considering only the export figures for the year 1919 (almost 6,000,000 pounds), approximately 24,000,000 pounds of the Egyptian crop would be left for home consumption, to which must be added a considerable quantity imported from India, China, and the Sudan.

Peanuts are used in the Near East in confectionery, but are principally consumed salted and roasted. Almost the whole crop which is consumed locally is used in this manner, a very small proportion being crushed for oil.

There is no indication of an increase in the production of peanuts in Egypt, as other crops are more profitable, and land which cannot be used for the more favoured crops and which can be used for peanuts is limited, as Egypt must depend upon irrigation for the watering of crops, and the irrigation canals do not extend into the sandy regions.

There are no modern peanut-oil mills in Egypt, although occasionally oil is expressed from peanuts. The amount thus produced is negligible, and none enters into the export trade, although a considerable quantity of peanut oil is imported from abroad. Labour saving machinery and other similar devices are not used in the production of peanuts, and no special machines are used for expressing oil.

FUTURE OF THE INDIAN CHEMICAL INDUSTRIES

Adequate development of many Indian industries is being hindered by the need of supplies at moderate cost of the chemicals required in those industries.

Of the requisite chemicals, sulphuric acid and alkali are those most needed. At present, practically every ounce of alkali used has to be imported, and it is therefore practically impossible to start an indigenous industry in which acids and alkalis are required in large quantities. A heavy handicap is thus placed on the manufacture of glass, soap and textile fabrics—all of which industries are capable of great expansion.

It is estimated that from five to seven million pounds sterling worth of oil seed is annually wasted for want of means for utilising it in the country. The imports of soap amount to nearly a crore of rupees in value, all of which could be produced in the country from cotton seed. Many soap works have been started; but their development has, for want of a cheaper supply of alkali, not been taken seriously in hand.

Unfortunately for herself, India does not possess extensive deposits of either sulphur or pyrites, with the result that the 4,000 or so tons

of sulphuric acid which are produced annually are manufactured from imported sulphur. India possesses, however, an almost unlimited supply of gypsum containing about 18 per cent. of sulphur, and it may be found practicable to recover this sulphur for use in the manufacture of sulphuric acid and alkalis. The gypsum may be had in some parts of India at a cost of only 8 annas per ton, and all other raw materials required for the manufacture of alkalis can be had in abundance.

If alkalis could be obtained at the price they command in Europe, it might be possible for glassworks in India to become successful propositions.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 p.m. : —

MARCH 1.—EMANUEL MOOR, "The Duplex-Coupler Pianoforte." PERCY A. SCHOLDS, Music Critic to the *Observer*, in the Chair.

MARCH 8.—W. A. APPLETON, C.B.E., Secretary to the General Federation of Trade Unions, "The Proper Functions of Trade Unions." JOHN MURRAY, M.P., in the chair.

MARCH 15.—OSWALD T. FALK, "Certain Aspects of the Problem of Exchange Stabilisation." SIR ROBERT M. KINDERSLEY, K.B.E., in the chair.

MARCH 22.—PRINCIPAL A. P. LAURIE, M.A., D.Sc., F.R.S.E., "The Permanency of Oil Colours." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., in the chair.

MARCH 29.—SIR THOMAS OLIVER, LL.D., D.Sc., M.D., F.R.C.P., "Alcohol in Relation to Industrial Hygiene." (Shaw Lecture.)

APRIL 5.—PROFESSOR ERNEST R. MATTHEWS, "Sea Encroachment and its Prevention." LORD HEADLEY, M.Inst.C.E.I., in the chair.

APRIL 26.—JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Jute Industry, as illustrated by its Application to the Jute Industry." SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the chair.

Dates to be hereafter announced :—

LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

PHILIP SCHIDROWITZ, Ph.D., F.C.S., "Recent Developments in India Rubber Manufacture."

MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock.

MARCH 24.—PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India."

APRIL 28.—F. G. ROYAL-DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the chair.

MAY 26.—PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow, Magdalene College, Cambridge. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced :—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION.

Tuesday afternoons, at 4.30 o'clock.

APRIL 4.—LIEUT. COLONEL SIR THOMAS BILBE ROBINSON, G.B.E., K.C.M.G., "New Zealand."

MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E., "Tanganyika Territory (formerly German East Africa)." Date to be hereafter announced.

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETINGS.)

Friday afternoons, at 4.30 o'clock.

MAY 5 PROFESSOR WILLIAM HENRY ECCLES D.Sc. (London), F.R.S., "Imperial Wireless Communication."

CANTOR LECTURES.

Monday evenings, at 8 o'clock.

ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., late Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington, "The Mechanical Design of Scientific Instruments." Three Lectures. February 20, 27 and March 6.

Syllabus.

LECTURE II.—FEBRUARY 27.—The Lower and Higher Pairs—Restraint against Sliding—Restraint against Rotation—Centroids and Axodes—The Design of Profiles.

LECTURE III.—MARCH 6.—The Elastic Nature of all Materials—The Elastic Constants—The Rigidity of Instruments—Manufacture—Models—Interchangeable Manufacture.

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester. "The Constituents of Essential Oils." Three Lectures. March 20, 27, April 3.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, FEBRUARY 27. People's League of Health, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Sir Maurice Craig, "Habit, Adaptation."

Mechanical Engineers, Institution of, Storey's Gate, S.W., 7 p.m. (Graduates' Meeting) Sir Henry Fowler, "Metallurgy in Relation to Mechanical Engineering."

Electrical Engineers, Institution of (N. Eastern Centre), Armstrong College, Newcastle, 7.15 p.m.

Architectural Association, 34, Bedford Square, W.C., 7.30 p.m. Mr. Hilaire Belloc, "The Probable Effect on Architecture of the Decline in our Civilization."

TUESDAY, FEBRUARY 28. Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Mr. L. Gaster, "Industrial Lighting—Ideal Requirements (Legislative and otherwise), and Practical Solutions."

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Miss R. M. Fleming, "Sex and Growth Features in Racial Analysis."

University of London, at the Imperial College, Royal School of Mines, South Kensington, S.W., 5.30 p.m. Colonel N. T. Belaisew, "The Crystallisation of Metals." (Lecture II.)

University of London, at the London School of Economics, Houghton Street, Aldwych, W.C., 6 p.m. Sir Josiah Stamp, "The Administrative Factor in Government."

Anglo-French Society, Scala House, Tottenham Street, W., 6.15 p.m. Mons. M. Thiery, "Le Theatre d'Emile Augier."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. T. Bell, "Present Day Portraiture."

Royal Institution, Albemarle Street, W., 3 p.m. Sir Arthur Keith, "Anthropology of the British Empire." (Lecture II.)

Electrical Engineers, Institution of (N. Midlands Centre), Hotel Metropole, King Street, Leeds, 7 p.m. Exhibition of Cinematograph Films, by Dr. C. C. Garrard and Mr. F. Gill.

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 7.30 p.m. Discussion on Recording Instruments for Motor Cars.

Royal Dublin Society, Leinster House, Dublin, 4.15 p.m. 1. Prof. J. Joly, "A New Method of Gauging the Flow of Rivers." 2. Mr. J. G. Rhynehart, "On the Life-History and Bionomics of the Flax Mea-Beetle (*Longitarsus parvulus* Payk.), with descriptions of the hitherto Unknown Larval and Pupal Stages." 3. Mr. E. J. Sheehy, "The Influence of Feeding on Milk Fat." 4. Mr. L. B. Smyth, "On a variety of Pinite Occurring at Ballycorus, Co. Dublin."

WEDNESDAY, MARCH 1. Public Analysts, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1. Mr. R. V. Wadsworth, "The Theobromine Content of Cacao Beans and Cocoa." 2. Messrs. A. H. Bennett and F. K. Donovan, "The Determination of Aldehydes and Ketones by means of Hydroxylamine." 3. Mr. R. E. Essery, "The Value of Fish Scales as a Means of Identification of the Fish used in Manufactured Products." 4. Messrs. N. Evers and G. D. Eldon, "The Examination of B. P. Ointments."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. H. Cousins, "The Purpose of Economic Activities."

Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Dr. C. E. M. Jones, "Surgical Tuberculosis in Children."

University of London, South Kensington, S.W., 5 p.m. Sir Frederick Bridge, "Sir W. Leighton's Great Collection of Early 17th Century Motets by Eminent English Composers" (Lecture IV.)

University of London, at the London School of Medicine for Women, Hunter Street, W.C., 5 p.m. Dr. H. H. Dale, "Some Recent Developments in Pharmacology." (Lecture II)

Electrical Engineers, Institution of (Wireless Section), Savoy Place, Victoria Embankment, W.C., 6 p.m. Messrs. E. B. Moullin and L. B. Turner, "The Thermionic Triode and Rectifier."

THURSDAY, MARCH 2. Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. W. D. Douglas, "Testing Aircraft to Destruction."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. 1. Mr. C. H. Wordingham, "The B.E.S.A. Specifications for Starters." 2. Mr. J. Anderson, "Electric Motor Starters." 3. Mr. W. Wilson, "Some Notes on the Design of Liquid Rheostats."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. W. M. Lefroy, "The Menace of the Insect Pest." (Lecture I.)

Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Dr. L. D. Barnett, "The Hindu Culture of India." (Lecture I.)

Auctioneers and Estate Agents Institute, 34, Russell Square, W.C., 7.45 p.m. Mr. W. H. Daw, "Insurance and Duties of Assessors."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Dyers and Colourists, Society of (West Riding Section), Lecture by Prof. J. W. McBain, (Leeds Junior Branch), Mr. D. T. McLellan, "Faults in Dyeing."

FRIDAY, MARCH 3. Fine Art Trade Guild, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7 p.m.

Royal Institution, Albemarle Street, W., 3 p.m. Dr. C. Morley Wenyon.

Chemical Industry, Society of (Manchester Section), at the Textile Institute, St. Mary's Parsonage, Manchester, 7 p.m. 1. Capt. F. S. Sinnatt, "A Contribution to the Study of the Oxidation of Coal." 2. Mrs. M. B. Craven, "On a Cause of Splitting of a Pottery Material."

Philological Society, University College, Gower Street, W.C., 5.30 p.m. Dictionary Evening.

Engineers, Junior Institution of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. E. T. Elbourne, "Factory Administration."

Royal Institution, Albemarle Street, W., 3 p.m. Sir Ernest Rutherford, "Radio-Activity." (Lecture I.)

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday of the week preceding the Meeting.

No. 3.615.

VOL. LXX.

FRIDAY, MARCH 3, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MARCH 6th, at 8 p.m. (Cantor Lecture.) ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., Professor of Optical Engineering and Instrument Design, Imperial College of Science and Technology, South Kensington. "The Mechanical Design of Scientific Instruments." (Lecture III.)

WEDNESDAY, MARCH 8th, at 8 p.m. (Ordinary Meeting.) W. A. APPLETON, C.B.E., Secretary to the General Federation of Trade Unions, "The Proper Functions of Trade Unions." JOHN MURRAY, M.P., in the chair.

THIRTEENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 22nd, 1922: SIR HERBERT JACKSON, K.B.E., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Basu, M. N., Calcutta, India.

Hayes, Sidney George, Ilford, Essex.

Orton, Charles James Swaffield, Broadstairs.

Rajhavan, S. Srinivasa, B.A., B.L., Madras, India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Gidney, Lieut.-Col. Henry A. J., F.R.C.S.,

D.P.H., J.P., M.L.A., I.M.S. (retired), Delhi, India.

Khan, Ghulam Mohd, Lyallpur, India.

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

FRIDAY, FEBRUARY 24th, 1922; VISCOUNT ELVEDEN, C.B., C.M.G., M.P., in the chair.

A paper on "Lignites and Brown Coals and their Importance to the Empire," was read by PROFESSOR WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S.

The paper and discussion will be published in a subsequent number of the *Journal*.

DOMINIONS AND COLONIES SECTION.

The Council have appointed the Right Hon. Sir Joseph Cook, G.C.M.G., High Commissioner for Australia, and the Hon. John McWhae, Agent-General for Victoria, members of the Dominions and Colonies Section Committee.

INDIAN SECTION.

The Council have appointed Sir Thomas H. Holland, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., a member of the Indian Section Committee.

CANTOR LECTURE.

On Monday evening, February 7th, PROFESSOR ALAN F. C. POLLARD, F.Inst.P., A.M.I.E.E., delivered the second lecture of his course on "The Mechanical Design of Scientific Instruments."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES SECTION.

TUESDAY, FEBRUARY 7TH, 1922.

THE RIGHT HON. LORD CLINTON in the chair.

THE CHAIRMAN, in introducing the author of the paper, Mr. W. Turnbull, said that every one who had had an opportunity of visiting the great forests of Western Canada would agree that they were amongst the most wonderful sights in the whole world. Most of the varieties of trees that were grown on the Pacific Coast were capable of being grown in this country and were familiar objects in our parks and woodlands, but the extraordinarily luxuriant development and the magnificence of the growth of those trees on the Pacific Coast made it difficult for one to realise that they were the same kind of trees as were seen in this country. Apart altogether from the æsthetic value of the forests, they were of enormous commercial importance, not only to the Dominion of Canada, but to the trade of the whole world, and every one must be interested in their conservation.

The paper read was:—

THE TIMBERS OF BRITISH COLUMBIA.

By WILLIAM TURNBULL,

Timber Commissioner for the Government of British Columbia.

I will try not to weary you with more statistics than are absolutely necessary. Therefore, I will simply state, without figures, the fact that, in spite of the increased use of steel and other substitutes for wood, the *per capita* consumption of timber is steadily increasing and is likely to do so. Our civilisation is ever finding new uses for wood and wood products, just as our remaining savagery-warfare recently found a wide variety of uses for timber.

Wood, therefore, is an increasingly important commercial and industrial commodity. To the Province of British Columbia it is vitally important. The huge stands of coniferous, or soft, woods along the freely indented coast line and in the interior of British Columbia constitute at present our greatest provincial asset. Our Government obtains a revenue of over three million dollars annually from its timber. To a population of only 700,000 people, a fair sized city population here, this amount is very important, particularly when one bears in mind that an amount equally large is required to meet our annual educational bill alone. You can readily understand, therefore, that we are intensely interested in our timber. It forms a large part of our life's blood, and the circulation of the life's blood of any portion of the Empire should cause at least a slight sympathetic throb here, in the heart of the Empire.

One of the lessons driven home by the war is the value of our Empire's timber. You remember the search for quantities of timber suitable for aeroplane construction and how it was finally discovered that British Columbia produced the type wanted in its light, but tough and strong, Sitka Spruce.

One of the results of this search for aeroplane stock and other timbers for war purposes was a general stock-taking of the timber resources of the Empire, culminating in the Imperial Forestry Conference in this city in 1920, from which has sprung the Empire Forestry Association.

According to the Whitford-Craig report, the only record we have to guide us, British

Columbia has a stand of commercial timber of 366 billion feet, roughly, 200 million Petrograd standards, or one-third of Canada's total stand. Of this total, 350 billion feet is of saw-log size, which, in British Columbia, is of 10in. top.

Roughly, two-thirds of this stand is on, or adjacent to, the coast, and the balance in the interior.

The total area of forest land in British Columbia is estimated at 149,000 square miles, of which 115,000 square miles are still in possession of the Crown, the balance being nearly equally divided between lands Crown granted and lands held under timber licence, lease or sales.

About one quarter of the estimated stand of timber is still in possession of the Crown. Crown timber is now disposed of only by tender, an upset price being set by the Forest Branch.

Our chief commercial timbers are Douglas Fir, Sitka Spruce, Western Hemlock, Red Cedar, Western Yellow Pine and Western Larch. Of these, you are chiefly interested in the first two, though our Hemlock ought to be better known in this country.

DOUGLAS FIR (*Pseudotsuga taxifolia*).

The most important of our woods is undoubtedly Douglas Fir, known throughout the world under various names, the chief here being Oregon Pine and British Columbia Pine.

As a matter of fact, Douglas Fir is, strictly speaking, neither a fir nor a pine. The name Oregon Pine, which, by the way, the Oregon people are seeking to revive in place of Douglas Fir, was first given to this wood by accident. Dr. McCullough, a Scotchman and the first Hudson Bay factor at Fort Vancouver in the territory of Oregon, named it Oregon Pine in this way: A schooner arrived from the Hawaiian Islands with sugar and a request to the company for a return cargo of timber. Natives were set to cut down the huge trees; saw them up, and load the vessel. McCullough's chief clerk asked how he should describe the timber in the manifest. The doctor, who was something of a botanist, said "It's neither Pine nor Fir, but it's nearer a Pine. Call it Pine." "What sort of Pine, sir?" asked the clerk. The doctor thought for a moment, and then said:—"This is Oregon, call it Oregon Pine." The name was picked up by sailing-ship captains who had to ship masts and renew spars on the Pacific Coast,

FIG. 1.—Douglas Fir and Red Cedar.

and the sailors carried it to every port in the world. The sailor was a great advertising agent, and his work still shows big results after all these years.

Early in the 19th century, David Douglas, a Scotch botanist, was sent out to the Pacific Coast by the Horticultural Society of England. Douglas found this magnificent tree; decided it was nearer a fir than a pine, and called it Douglas Fir, which is now its recognised trade name all along the

coast. In this country, you seem to prefer the term pine, largely, I suppose, because of your high regard for the Yellow or Pitch Pine of the Southern States. There may not be much in a name, but we sometimes find a good deal of trouble in two names, and it is not surprising to find people who believe that Oregon Pine and Douglas Fir are two distinct species. Men in the timber trade have told me that they did not handle Douglas Fir, but that they liked

Oregon Pine. They are one and the same tree.

British Columbia has 76 billion feet of Douglas Fir, which comprises 21.7 per cent. of our total commercial timber stand. It is the most important tree on the North American continent and grows to enormous size, as you may judge from the single-stick flagstaff now in Kew Gardens. We have Douglas Fir trees 300 feet high and 15 feet through at the butt. Commercially speaking, of course, average sized second growth timber is more valuable. We naturally use a great many adjectives about it, but one cannot over-emphasise the good qualities of one's best friend, and Douglas Fir is British Columbia's best friend.

It varies in colour from a straw-yellow to a reddish-brown; is moderately hard, yet easy to work, straight-grained, tough, resilient and durable. It takes stains well, holds nails firmly and does not worry about water.

The great value of Douglas Fir is in the wide variety of uses to which its lumber may be put. Its great strength, coupled with comparatively light weight, makes it ideal for heavy structural work, such as supports in large buildings, bridge and ship timbers, framing for houses, planking for scows, dredges, etc. It is also equally suited for all dimension material, such as joists, scantling, etc., in any kind of building to be exposed to any kind of weather.

We have in British Columbia houses built of Douglas Fir sixty years ago still occupied and in good condition—and the climate of British Columbia is not particularly dry in fall and winter. We find Douglas Fir remarkably durable.

Your Great Western Railway Company has furnished us with evidence of the durability of this wood when creosoted and used for sleepers. Out of 616 sleepers tested only 23 were removed on account of decay in 17½ years.

You may be interested to learn that city engineers in Canada and the United States are to-day giving exactly the same working stresses for Douglas Fir and Pitch Pine, after years of experience of both woods. Hundreds of tests carried out by the U.S. Forest Products Laboratories show Douglas Fir to be equal in strength to Southern Pine, in fact, in elastic limit to be 10 per cent. stronger. Douglas Fir is the strongest wood in the world, for its weight. Railroad companies in Eastern Canada

use much of it in car construction for sills, etc.

Besides being invaluable as a structural timber, Douglas Fir, sawn edge-grain makes a very fine flooring, wearing evenly and taking a splendid polish.

In Canada we use much more wood-panelling in our houses than you do here, and for this purpose and other interior finish, Douglas Fir is the most popular wood. The figuring is distinctive, and when the grain is fine and "curly" a remarkably beautiful effect is obtained. It finishes and polishes splendidly. The best effects are of course, obtained from veneer cut panelling as panels may be matched very closely.

SITKA SPRUCE (*Picea sitchensis*).

We now come to Sitka Spruce, the best known of our spruces. It is found throughout the Douglas Fir region, but is at its best on the north of Vancouver Island and north of the fir belt on the Queen Charlotte Islands, particularly on Graham and Moresby Islands of that group. From Graham and Moresby Islands, British Columbia shipped, during the war, enough Sitka Spruce to construct 20,000 aeroplanes. Your timber research men here found that Sitka Spruce met their requirements of lightness with strength, toughness, even grain and freedom from splitting. When active fighting ceased, the Imperial Munitions Board immediately dropped operations and lost all interest in Spruce. Many millions of feet of the cream of our Spruce lay in the woods and the water, the latter subject to teredo attack. This large stock of splendid material was ultimately sold at salvage prices to be sawn into lumber and chewed up into pulp to make paper. Possibly this was the best plan of disposal at the moment, but it seems a pity that such quantities of valuable aeroplane stock should be devoted to giving racing results to the public. I venture to think that the Germans or the Japanese would have valued it more highly.

I say it seems a pity that its world value should so soon have been lost sight of, just because active fighting suddenly ceased. The war did *not* end on November 11th, 1918, any more than it began on August 4th, 1914. The struggle for world supremacy began soon after 1871 and is still proceeding. True, military efforts ceased in 1918, but the struggle continues

FIG. 2.—Sitka Spruce Stand on Queen Charlotte Islands, B.C.

in marks, francs, pounds sterling, dollars, and yen, in commerce and industry. Shall we require that spruce again? One wonders.

To-day, much Sitka Spruce is going into pulp, but it is also being made into boxes of all sizes. Its freedom from taste or smell makes it invaluable for containing foodstuffs. It is also being used for framing, sheathing, and sub-flooring, while it is more than useful as core stock for veneered articles. It is also one of the most resonant of woods because the fibres are long and regularly arranged, and is now being used in making piano sounding boards, and cabinet gramophone horns; I find in Britain that it is in high favour with violin makers.

Like most British Columbia woods it is obtainable in large sizes, much of it clear.

WESTERN HEMLOCK. (*Tsuga heterophylla*).

Western Hemlock is not so well known over here as it is in Canada. It constitutes 18.3 per cent. of our commercial timber and, like the others, grows to large size. Even in Canada, its good qualities and value are not so well known as they will be. To-day, much of our Hemlock goes into pulp, for which it is admirably suited, but, for ordinary building purposes it is just as useful as Douglas Fir. It has 88 per cent. of the strength of its bigger brother and is not so suitable for the heaviest type of construction, but it makes excellent siding, flooring, ceiling, scantling, inside joists, etc. For sash and door fixtures, turned stock, panelling, etc., it has exceptional merit.

Western Hemlock is usually light in colour and contains no pitch or resin. It dresses to a smooth satin-like surface capable of taking a very high polish and is not easily scratched. Sawn slash grain, it shows a very handsome figuring.

I notice that you are fond of enamelled woodwork in this country. Western Hemlock takes enamel finish to perfection.

Edge-grain Hemlock flooring has proved invaluable. It hardens with age and we have an instance on the Pacific Coast where it has been down for 50 years and is now so hard that it is difficult to drive a tack in.

Canadian railway companies are using it for car flooring, siding, etc., and find it highly satisfactory.

The Japanese, who use large quantities of our fir and cedar, have become aware of the good qualities of Hemlock and are now asking for it.

Toronto Harbour Commissioners have put seven million feet of our Hemlock into Harbour work in the past few years, and the Dominion Government are using it in construction of part of their big dry dock at Esquimalt, near Victoria, British Columbia.

It is also very popular as a box and packing case material. One firm on the Coast is shipping 50,000 oil cases of Hemlock to Singapore every month.

Incidentally the Hemlock bark is very rich in tannic acid, but this industry has not been developed yet on the Coast.

RED CEDAR (*Thuja plicata*).

Western Red Cedar, another of our giants, is not much used in this country, but is a very important wood. In some ways it is more important than any of the others. It is the overcoat for our houses, in the form of roof and siding shingles, and, while I may be prejudiced, I believe they are much more artistic as a house covering than slates or tiles, while they keep out the heat in summer and the cold in winter. Rain or snow on a shingle roof is like water on a duck's back. Red cedar may, with the Southern Cypress, be described as the "wood eternal." Trees which fell in the damp woods of British Columbia centuries ago are found to-day perfectly sound and fit for shingles and lumber. It was from the Red Cedar that the Indian hollowed out his war canoes, split planks for his lodges, and carved his historic totem poles,

and his judgment was sound as usual. (The Totem pole must have been the origin of the term "family tree.")

The wood is exceptionally light, soft and of close, straight grain, making it easy to handle and work. It is remarkably free from warping, shrinking or swelling. The narrow sapwood is white, and the heartwood runs from a light yellow to brownish-red. It is invaluable for all outdoor work as all weathers are alike to Red Cedar. It is our great fence and pole material, requiring no treatment or preservative. The butt will stay sound for years and years under any conditions, and for siding, lattices, pergolas, arbors, summer houses, green houses, etc., it is unequalled.

It is also very effective in interior work though its softness renders it liable to denting in low panelling. For beam ceiling work it is exceedingly handsome. Finished naturally, it acquires with age a silvery silky sheen which is very beautiful.

One of the great qualities of the British people is loyalty to old friends. An inherent part of this loyalty is a slowness in making new friends, even in woods. When a new timber acquaintance is adopted they do not like to admit the newness of the friendship and very often dress up the new-comer to resemble an old friend. For instance, I have seen here some magnificent panelling of British Columbia Red Cedar, but British Columbia timber men would scarcely recognise it. It is beautifully dressed, but disguised so as to resemble mahogany. It has not the mahogany quality; and it is ruined as cedar. Our Red Cedar, when finished naturally, mellows with age and takes on a beautiful silvery sheen, but a mahogany overcoat hides all this for ever.

We have another cedar--the Yellow Cedar or Cypress--which is not at the moment of commercial interest. It is found only in scattered stands, above the 2,000 feet level on the lower coast, but at tidewater farther north. It is similar in outward appearance to the Red Cedar; the wood is sulphur-yellow in colour and is the heaviest and most durable coniferous wood in the Province. It is easily worked and takes a beautiful satin-finish, which renders it especially useful for finish and cabinet work.

It is practically unaffected by atmospheric changes and is very valuable for boat-building, greenhouses, battery separators,

etc., and is said to be immune against the teredo. The latter statement I cannot vouch for. There is a considerable quantity on the Queen Charlotte Islands, but it is being logged only incidentally and is very hard to get. Clear Yellow Cedar makes a very high price.

COTTONWOOD (*Populus trichocarpa*).

Another interesting wood is our Black Cottonwood. It is found in river bottoms on Vancouver Island, along the Fraser River Valley to Prince George and in the Skeena and Naas River districts north and east of Prince Rupert, the terminal of the Grand Trunk Pacific Railway. It is the only deciduous tree in British Columbia which is of commercial value.

The wood is grayish-white, soft, odourless,

tasteless, straight and even grained, very light, long fibred and easily nailed, glued and veneered. It is an ideal box material and its great strength, compared with its light weight, renders it especially valuable in making laminated wood products.

It is now in demand for carriage and automobile bodies, and in the near future will be much more highly valued than at present.

These, with the exception of the small firs, which we do not consider as individually of great importance, comprise our chief commercial woods adjacent to tidewater.

INTERIOR WOODS.

Our interior woods, though of great value to British Columbia, are too far from the ocean to be brought over here successfully.

FIG. 3.—Logging Operations in British Columbia.

The most important of these are the Western Soft Pine, and Western Larch. They are the important woods of the southern interior of the Province, but I do not propose to deal with them in detail.

LOGGING.

The improvement in logging methods is a clear index to the increased timber business of British Columbia.

In the "seventies," when the Government's annual revenue was about \$600—roughly £120—teams of heavy oxen provided the motive power. The spark was supplied by the teamster who, in addition to a business-like hickory goad as his badge of office, had a command of sulphurous language which seemed to burn its way into the brain of even an ox. Increased demand required greater speed and horses and mules superseded the oxen. Mule-driving also required high-power language.

To-day, steam has ousted the horse and mule, and is now being helped out by the motor tractor.

The logging superintendent of to-day carefully maps out his timber area in profile; selects his "spar-trees" at strategic points, and lays out his main railroad line and branches. Besides knowing his timber, he knows every "kink," rise and fall in his area.

The donkey engine and high "spar-tree," with rigging attached, alongside the loading track with its train of skeleton flat cars, are the central features of present-day logging operations in British Columbia. From a radius of 1,200 to 1,500 feet huge logs are hauled by overhead cable from off the mountain slopes to the cars just as easily as a trout is brought to landing net on a line.

Logging is no longer confined to timber close to tide-water, and logging railways run back into the woods from ten to thirty miles. Train-loads of logs are brought down; dumped into the sea, formed into booms and towed to the mills. Booms of logs are towed long distances and, in the land-locked coast waters, the percentage of loss is small.

The Davis patent whale-back rafting method is also used successfully, but the old sea-level boom is still the most popular.

From a timber conservation standpoint, our logging methods are extravagant and visitors from Europe are apt to hold up

their hands in horror at the amount of waste left in the woods. We are a young country, and the young are not apt to think much of the distant future. Some one has said "Happy is the nation which has no history." We are somewhat in that happy position, but it has disadvantages, one of which is a light regard for posterity.

However, there is usually a reason for everything and, paradoxical as it may seem, the reason for our extravagance in the woods is economy. In British Columbia, labour, food, logging machinery and equipment and towing costs are high. It costs as much to get the skimmed milk as the cream, as it were. We have been in the habit of looking on our forest resources as inexhaustible, and have acted accordingly.

We have been "mining" timber instead of cropping it, but the day is at hand when we must think of future crops, and our Forest Service is taking steps towards that end. Just recently the Hon. T. D. Pattullo, Minister in charge of that Department, spent some time in Sweden looking into Swedish methods.

FOREST SERVICE.

Our Forest Service was inaugurated in 1912; the war broke out in 1914 and our staff became a mere skeleton, but we have now reorganised on a stronger basis than before.

On the British Columbia coast we have prolific forest reproduction and the young growth makes rapid progress, so that reforestation in many parts can be safely left to nature. Eighty per cent. of our energy and expenditure is devoted to protection from fire. Huge areas have been burned over in past years, and repeated burning ruins the seedbed; it is most important that we should keep down forest fires. To this end we employ a large staff of fire rangers every season. We have 80 automobiles in this service, armed with the latest type of fire-fighting pump, six seaplanes for reconnaissance work on the coast, and a fleet of fast launches. These launches are fitted with wireless telephones, in constant touch with wireless telephone stations along the coast right to headquarters in Vancouver. Headquarters, therefore, knows just what the fire situation is at any time and is immediately able to direct a force of men to any danger point.

FIG. 4 — Hotel built of Douglas Fir, with roof of Red Cedar Shingles.

OUTPUT AND MARKETS.

British Columbia has over 400 saw mills, ranging in capacity from 5,000 to 200,000 board feet per shift, and including the largest sawmill in the world. Over 50 per cent. of the mills are on the coast and they manufacture 80 per cent. of the total cut.

The huge logs are handled by powerful machinery, not being touched by hand until sawn into lumber.

British Columbia's annual timber cut is about two billion feet, or about one million Petrograd standards. Our annual natural increment is estimated at five times this quantity, hence the eagerness to extend our markets. We have a large but variable market on the Canadian prairies; a large and steadily growing outlet in Eastern Canada and the Eastern States, but we look to overseas markets for much of our future growth, and we think we are not looking in vain.

Our overseas trade has grown from 43 million feet in 1916 to 170 million in 1921. Of this amount Japan and China took 93 million feet, Australia and New Zealand 27 million, the United States 14 million and the United Kingdom nine million, the remainder going to Egypt, South Africa, India and South America. From these figures you will gather that our logical

market is on the Pacific, though there is still much business going from here to the United States which might just as easily be placed in British Columbia. Were British Columbia located where Sweden is, she would undoubtedly supply the United Kingdom with all her soft woods.

However, we are hopeful of shipping increasing quantities of timber here, as the Panama Canal has brought us nearly 6,000 miles nearer to this market than we used to be. We are able to market clear timber in much larger sizes than can be obtained in Europe, but the largest demand here is for lower grades, which, under normal conditions, will not stand the freight from the Pacific Coast though rates are now getting to a figure which opens up greater possibilities.

One handicap our manufacturers labour under in this market is that, in addition to the short haul from across the North Sea, they have also to contend with Swedish specifications. As you can judge from our forest scenes, British Columbia logs cannot be cut to length to order. We are cutting down primeval forests of timber of immense size, not harvesting a crop of uniform size and grades.

In Sweden they can afford to take time to carry out every operation scientifically

to the most minute detail. In British Columbia, with our high costs and long haul, we must make speed of production our first aim.

Our large business has been a home rail business, and our methods have been based on the requirements of our largest market.

Our proportion of British business has not been large enough to stimulate enthusiasm and keen interest amongst our manufacturers. The distant British market has not been capable of absorbing more than a third of our log; therefore, largely increased trade here meant either over-loaded yards or flourishing business in common grades at home. However, we are shipping more timber here than we did, and what would mean a little more to you, means a great deal more to British Columbia. We are closer together in every way than ever before, and we confidently look for an increased interest on both sides.

PULP AND PAPER.

In closing, I should like to say a little regarding our pulp and paper industry, which is still in its infancy, but is a very healthy, sturdy youngster.

We have four pulp and two paper plants, and production has grown from practically nothing in 1912 to an output of 136,832 tons of newsprint; 9,792 tons of wrapping; 5,300 tons of sulphate and 9,000 tons of sulphate pulp in 1920.

With abundant water-power, supply of 180 billion feet of timber saw-log size of species suitable for pulp, large stands of young growth working day and night from spring to fall to attain pulping size, and splendid harbour facilities, this industry is capable of enormous development.

Five new pulp companies are preparing to start operating and more will follow. Pulp stands in Eastern Canada and the Eastern States are being rapidly depleted and the attention of the manufacturer and the capitalist is turning to the west.

We are naturally optimistic in British Columbia, and we have ample grounds for our optimism.

DISCUSSION.

THE CHAIRMAN (LORD CLINTON), in opening the discussion, said he was sure all those present had listened with very great interest to the paper, which, with the excellent film that had been shown, had given a very good idea of the

immense work connected with the forests of British Columbia. At the beginning of the paper there was a reference to the constantly increasing consumption of timber per head of the population, and that was going on in spite of the many substitutes for timber for construction purposes that had been found. He had the honour to be a member of the Forestry Commission, which had to consider very carefully from what sources the future demand for timber in this country was going to be satisfied. The great forests of British Columbia were among the last great stands of coniferous timber. The natural timber available in the forests of the world was at one time supposed to be practically unlimited, but it was perfectly clear now that those forests, partly on account of their use for commercial purposes and partly on account of the great enemy, fire, were certainly exhaustible. It was impossible for any one to tell what their actual life would be, but it was necessary to look forward to a time when the imports of timber into this country must decrease. It could not be expected that the efforts of man would ever rival the ancient timbers that had been used from those forests in the past, and unfortunately at the present time not only had the axe been laid to the root of the tree to demolish those forests, but the 'axe' had been laid to the root of the finances by means of which it was hoped to grow forests in this country. Efforts would, no doubt, be made to carry on the work, but, in view of the fact that the ordinary supplies of timber to this country from the New World and, most important of all perhaps, from Russia were disappearing, the outlook was not a happy one. He thought it would be of interest if the author could state what would be the probable increase of imports of timber into this country from Canada. He understood from the figures given by Mr. Turnbull that this country consumed about 9,000,000 board feet of timber per year from British Columbia, but it was quite certain that very much more than that would be required in the future. Our chief competitors for that timber were on the Pacific Coast, and he supposed the natural market for it would be the Southern States of America, which were coming to the end of their own timber supplies. The opening of the Panama Canal would, of course, be a great factor in bringing the timber to this country. There was one other point upon which he would like to touch, because it was of importance to those who were dealing with timbers in this country in relation to the vast area of Empire forests, which amounted to about 1,200,000,000 square miles—namely, the nomenclature of timbers. At the Forestry Conference held in this country two years ago our foresters talked in quite a different language in trees from the overseas foresters abroad, especially those from Canada. The latter used largely the trade names, which, as the author had said,

were arrived at in a haphazard way, while in this country the botanical names were generally used. The tree that was known in British Columbia as the Sitka spruce came into this country as spruce, but the name "spruce" was generally used here for the spruce of Norway and other parts of Europe, which was quite a different timber. The Sitka spruce was certainly going to be of great value in this country, and the Forestry Commission now had many millions of young plants in their plantations. Again, the author spoke of hemlock, which was a very familiar tree in this country, grown under the name of *Tauca Albertiana*. It was valuable not only for its beauty in our parks, but for its sylvicultural characteristics, which made it worthy of more cultivation than it had had up to the present time.

PROFESSOR PERCY GROOM, D.Sc., said the author was to be congratulated on the interest and importance of the paper. Personally, he would venture to emphasise the importance of British Columbian timbers by reference to only two timbers, the Douglas fir and the Sitka spruce. If one thought of the supplies of large dimensioned constructional timber in the world and left out of account the problematical large Scotch pine of the Northern Russian dominions, there remained only two coniferous timbers that could yield us big constructional logs, i.e., the Douglas fir and the pitch pine. The author had stated that ten years hence, according to an American authority, there would be no more pitch pine exported from America, so that the supplies of that big timber were being exhausted. When that exhaustion was complete there would remain in the world only one stock of the large dimensioned coniferous timber, i.e., the Douglas fir. When that, too, was exhausted there would never be any more in the world, so far as could be judged by modern forest policy, for that policy was to obtain the maximum return at a short rotation of about 70 years. Therefore British Columbia had got a very remarkable and indeed a unique treasure, and one wondered very much from an Imperial point of view what she was going to do with it. With regard to the second British Columbian timber with which he proposed to deal, the Sitka spruce, which the author pointed out was used during the war as an aeroplane material under the name of "silver spruce," that timber was of vast importance, because it had that unique combination of elastic and strength qualities and what was fundamentally important, excessively slow growth, narrow rings, that made it at any rate an unrivalled aeroplane timber at the present time. When that stock was gone he did not know where any other existed that could take its place. The question was, Would it be needed? Some people said that in the future aeroplanes would be made entirely of

metal. Assuming for the moment that an all-metal aeroplane was superior, it must be remembered that wood was a semi-manufactured material and that by the aid of a few simple machines and very unskilled labour—the labour of girls—the complete parts of an aeroplane could be manufactured. Therefore, he could not help thinking that timber would be a very valuable accessory material even if metal aeroplanes were used in the future. One other use of the Sitka spruce deserved consideration, because it might provide this country with a means of capturing a key industry. The author had mentioned in his paper the use of Sitka spruce for piano sounding boards and for violins. It must be remembered that the most careful workmanship and the best design would not make a good piano if there was a bad sounding board. Before the war the European sounding boards were made of the ordinary European so-called Norway spruce, and the best of that timber came from a definite height up the mountains, being easily recognisable by certain characteristic markings that could be identified with the naked eye. That very best material, which was formerly grown in Switzerland, France and Germany, had receded from those countries and was now left only in the vicinity of Roumania, so that the European supply of piano sounding board of the best quality was doomed to extinction. It was, like the Sitka spruce, a very slow-growing tree. In the past, he believed, Germany had the complete control of the best quality, the high merit of the German pianos being due to that control and to the fact that the manufacturers did not mind what they spent so long as they got a good sounding board, whereas the manufacturers in this country were prone to prefer buying cheap sounding boards, regardless of the tone resulting. During the war many samples of British Columbian spruce passed through his hands at the Air Ministry, and he was delighted to find that in British Columbia there was a considerable stock of the peculiar piano sounding board spruce, with its characteristic markings. Its elastic properties conformed with its structure. He hoped that the Government of British Columbia would bear in mind the enormous wealth that might be represented by that particular timber.

LIEUT.-COL. SIR DAVID PRAIN, C.M.G., C.I.E., F.R.S., said he had listened to the paper with much profit, but not with unmixed pleasure. With regard to what the author had said about the various individual trees, he felt very interested and had learned much. But when the question of logging was dealt with that was a very different matter, and Mr. Turnbull had himself frankly admitted the delinquencies of his country and had said that from a timber conservation standpoint the logging methods adopted in British Columbia were extravagant.

He felt he must criticise those who were responsible for the use of the word "illimitable," in connection with the forests of British Columbia, on the Government film that had been shown. That adjective was not applicable to the forests of any country when men exploited them. As a matter of fact, it was our enemies rather than our friends that we liked to hear boasting about the output of their timber and the rate at which they were exporting it to countries that were not friendly countries, or, if they were friendly, were trade rivals of our own. The beautiful pictures that had been put on the screen showed very clearly the extraordinary skill with which the logs of which the British Columbian hillsides were being denuded were handled and taken away, but—he did not know whether intentionally or through an oversight—no picture was shown that gave the faintest idea of the effect upon the hillsides so treated. It would have been interesting to see a picture of some of those hillsides after the timber had been taken away from them. With regard to the question of pulp, he was very sorry to hear the author boasting about the increase in the output of pulp, of which British Columbia seemed to be so proud. He would like to ask the author what was done with that pulp and also what it was made of. He thought the time was coming when the various communities interested in the matter would have to forbid pulp being made from the timber of any tree that was of the slightest use for any other purpose. The bulk of the pulp used was employed for an ephemeral purpose, for making paper for tradesmen's circulars and for daily newspapers and such things. The question of the disposal of pulp was a most serious one, and he thought that Governments which had the interests of the communities they governed at heart would have to take steps to say what might and what might not be used in the way of timber to produce pulp that was to be employed for ephemeral purposes.

MR. J. S. CORBETT (Secretary of the Empire Forestry Association) said he had had the privilege of listening to many papers on the timbers of the Empire read before the Royal Society of Arts, and he thought the present paper was one of the most valuable. After hearing them he had come to the conclusion that there were within the Empire sufficient timbers to meet the needs of Great Britain and that those timbers were equal, if not superior, to those produced by any other countries in the world. He thought the papers should be followed up, and that it was important to get into touch with all those who were responsible for the use of timber in any shape or form, and to bring home to them the information contained in those valuable papers. It was known from the statistics published that the value of timber and timber products im-

ported into this country in 1920 was £120,000,000 and of that amount probably 80 per cent. came from without the Empire, and yet there was timber within the Empire which ought to be used, and probably would be used if only its properties were appreciated and pressure brought to bear upon the Government and upon public bodies concerned with the use of timber. The streets of London were paved with timbers, the majority of which came from Scandinavia, but he was glad to say that within the last twelve months Canadian spruce had been specified for the first time. In England, also, there was timber which was equally suitable for paving-block purposes as was the imported Scandinavian. He thought what was required was a really sound business organisation to get into direct touch with those who were responsible for the drawing up of contracts where timber was concerned. The reader of the paper had referred to the Imperial Forestry Conference which was held in 1920, and also to the Empire Forestry Association as being one result of that conference. Personally, he happened to be the first Secretary of that Association, and he felt that, as Mr. Turnbull had said, there were enormous possibilities before the Association, provided it could obtain the confidence of all those who were interested in the production and exploitation of Empire timbers and provided also that it could receive sufficient funds to enable it to carry on the work it had undertaken. The Chairman had referred in his speech to the possibility of the grant to the Forestry Commission being reduced. It should be realised that probably three-quarters of that grant was spent on British labour, and the grant was being utilised to provide work for some of the unemployed at the present time, and it seemed incredible that there should be any suggestion that that small grant, which he believed was to be £200,000 for the next year, should be criticised in any way, considering the enormous importance of the subject. The Secretary of the Australian Forest League told him recently that the League exercised a very considerable influence on the election of the Australian Legislature. Could one imagine any aspirant for Parliamentary honours in this country being heckled on the subject of forestry by one of his constituents at a public meeting? Australia exported timber to the value of about £2,000,000 per annum, and yet Great Britain, which imported timber to the value of over £100,000,000 per annum, had no forest conscience and took little interest in forestry problems. He hoped the Empire Forestry Association would be able to create a real forest conscience amongst the general public and make them realise the importance of timber problems. The author had not referred in his paper to the resolution which was passed at the Imperial Forestry Conference with reference to the establishment of the Imperial Forestry Bureau.

If the work undertaken by the Empire Forestry Association was to be a success, he thought it was absolutely necessary that a permanent exhibition should be established of timbers of the Empire, which were a commercial proposition. All the mahoganies should be grouped together, the teaks, the soft woods and so forth, and information should be available as to their tests, the probable price and the quantity that was available. If there was such an exhibition, he believed it would be possible to secure the interest and confidence of architects and others responsible for the drawing up of the various contracts. Another thing which he thought was necessary was information as to the consumption of timber by the large railway companies, shipbuilders, harbour boards and municipalities. That information should be drawn up under certain headings, such as the quantity, the species, the price paid and the source of origin, and it would then be possible to ascertain whether timbers from within the Empire could be substituted for those which were now imported into this country from without the Empire. He had recently had an opportunity of inspecting some harbour works in the north of England, and he found there greenheart from Cuba being used, whereas British Guiana was asking for an outlet for her greenheart. The greenheart from the Colonies could be supplied at less cost than the contractor was paying for Cuban. He found also that bridges were being paved with the very finest pitch pine, and he was sure there must be within the Empire timbers which were equally suitable for that purpose. The exhibition having been established and the information he had suggested having been secured, the next step to be taken was to form a central clearing house for information on all matters relating to forestry problems, and information such as the author had given on the present occasion and such as had been given before the Royal Society of Arts on previous occasions must be spread broadcast and an effort made to interest the public in the importance of the problem.

MAJOR F. M. OLIPHANT (Department of Scientific and Industrial Research) said he had lived in British Columbia and worked in timber mills there, and there was one remark he would like to make with reference to the western hemlock mentioned by the author, and also with reference to the Chairman's remarks on the confusion that existed in the timber world owing to the difference in nomenclature in different countries. In Western Canada the western hemlock was used, and in Eastern Canada there was a timber called the eastern hemlock. The two were different species, the western hemlock being the *Tsuga heterophylla* and the eastern hemlock being the *Tsuga canadensis*. The western hemlock was

a very fine timber; it had a straight grain and was cleaner, harder, more durable than the eastern hemlock, and without its brittleness. Its properties in general were very much more suitable for work where good timber was required and certainly for interior work, than those of the eastern hemlock. The eastern hemlock was very rough and knotty, it warped and shrank, it was coarse and crooked in grain and very brittle. The only good property he had ever heard attributed to it being that it lasted very well under water. As far as he could recollect, it used to be employed in British Columbia for the forms used in reinforced concrete buildings and for rough general constructional purposes. Unfortunately, people in this country and in Canada sometimes complained that hemlock timber was useless, when their knowledge of that timber was confined to the eastern hemlock.

MR. BYRON BRENNAN, C.M.G., in proposing that a hearty vote of thanks be accorded to the author for his valuable paper, said he was confident that every one present had listened to the paper with great interest. He did not quite agree with Sir David Prain in deploring the use of timber for making pulp. After all, the paper on which the proofs of the author's paper were printed might be made of British Columbian pulp, and he was sure nobody would say that that paper had been used for a subject of ephemeral interest. In addition to thanking the author, he would like those present to show their appreciation of the kindness of Lord Clinton in sparing so much of his valuable time to come and preside at the meeting.

SIR GEORGE HART, K.B.E., C.I.E., in seconding the motion, said that Sir David Prain had already referred to the one point in the author's very able and interesting paper, to which he would have liked to draw attention. The author had shown on the screen pictures of the wonderful and remarkable way in which forest products were dealt with in British Columbia; but, to put it in quite plain English, he thought this amounted almost to forest destruction, as, indeed, the author had practically admitted. It was evident that British Columbia formed what might be termed the storehouse of the Empire for coniferous timbers, just as India, perhaps to a less extent, formed the storehouse of the Empire for hard wood timbers. India was conserving its forests and working them only to the extent to which they should be worked; but he feared that British Columbia had not yet adopted that policy. It seemed to him very important that attention should be paid to this point, because, if nothing was done to secure regeneration to the proper extent, it was quite certain that never again would the forests of British Columbia contain the same proportion of valuable timber as they possessed before they were cut down.

The resolution was carried unanimously.

MR. W. TURNBULL, in reply, said the Chairman had asked if he could give an estimate of the possible demand of this country on the timber of British Columbia. That was a very difficult question for him to answer. He thought the estimate could only be made by the men engaged in the timber industry in this country; he had asked them what the possibilities were and they said: "Give us the timber at our price and we will buy it." It was a matter of the price of the goods—a purely commercial question. In 1919 British Columbia sent to this country some 47,000,000 ft. of timber, whereas in 1921 about 9,000,000 ft. were sent. He thought the latter figure was the normal amount sent just now: 47,000,000 ft. was abnormal because it included timber bought as a war measure. Mr. Corbett pointed out that Great Britain imported £120,000,000 worth of timber and timber products per year, and, as he had stated, British Columbia sent about 9,000,000 ft., which would be about 180,000 dollars' worth. That might be some guide in forming an estimate, but he really could not attempt to make any estimate himself. It was purely a matter of commerce, and there was one point he would like to make in that connection. The large, clear grades of timber that could not be obtained from Norway and Sweden could be sent to this country from British Columbia because they could stand the freight, and that timber represented 30 per cent. of the British Columbia product. The common grades from that country would not, under normal conditions, carry the freight from the Pacific Coast to England. If the people in British Columbia received an order from this country for 20,000,000 ft. of absolutely clear timber they would not accept it, because that would leave them with 40,000,000 ft. of common timber in their yards over and above their ordinary amount of common timber. They would require to have an abnormal home market for common grades to the extent of 40,000,000 ft. if they were to supply this country with 20,000,000 ft. of clear wood. A lumber manufacturer might be running a door factory—doors in Canada being made of clear stock, unpainted—and when business was good for clear timber that manufacturer would have to limit the quantity he would permit his door factory to use. He was very much interested in the Chairman's remarks about nomenclature. Personally, he avoided the botanical names as much as possible and kept to the trade names. Even in the botanical names there were differences in different countries. For instance, the tree known as Douglas fir in this country was called *Pseudotsuga taxifolia* in British Columbia, and *Abies Douglasii* and *Pinus Douglasii* in this country. Commercial men simply used the trade names. With regard to Sir David Prain's remarks about the use of

valuable timber for making pulp to be used for an ephemeral purpose, strictly speaking, whenever timber was used for any commercial purpose it must be used for an ephemeral purpose. In the United States pulp was used for making the most beautiful furniture, basket chairs that closely imitated the Japanese wicker chairs, and twine, sacking and even clothing. He did not see any difference between using soft wood for such purposes and using it for street paving blocks. From an æsthetic standpoint it was a shame to cut down a single tree from the hills of British Columbia, but from the commercial point of view he could not see any difference between pulping it and sawing it into lumber or using it for any other commercial purpose. With respect to procuring timber from countries within instead of outside the Empire, that was purely a matter of business. About six months ago he had a discussion with the manager of a company that controlled the buying of timber for paving the London streets, and so far as he could recollect that gentleman told him that the streets in the city of London consumed about 20,000 standards of Baltic timber a year. That gentleman knew the Douglas fir and the Sitka spruce of British Columbia, and said: "If your lumber men can sell us their wood at a cheaper price than we pay for the wood from Norway, they will get my business." With reference to the amount of waste in the woods, a great deal of what was wasted was young growth that would not be commercially useful. A hillside might look very much like the battle fields of France, but the waste appeared worse than it really was, as so much of it was stuff that was of practically no value. It was a very difficult matter to control. New logging regulations had been framed in British Columbia, and the intention was to adopt more conservative methods of cutting. Only about one-fifth of the annual natural growth was cut, but the timber that was cut was mature timber, and there was no doubt that it would take a long time to replace that. Afforestation was being studied in British Columbia, but it would be impossible to produce the old mature Douglas fir that nature had provided, although afforestation would ensure a really commercial type of forest. If all the timber that existed at the present could be cleared off in about a hundred years' time and replanting carried out on the Swedish basis, more timber would be grown than could be cut. The logging men in British Columbia were very conservative, and if a logging superintendent was told that he ought to leave seed trees at certain points he would laugh at the idea, but both the logging men and the sawmill men had become much more interested in forestry than they ever were before. Commercial timber men had been brought to the stage when they realised that there was a real relationship between forestry and sawing lumber.

The meeting then terminated.

MR. G. M. RYAN, F.L.S., late India Forest Department, writes in support of Sir David Prain's views on the use of British Columbian timber for paper making:—

If there are grasses and shrubs already growing wild within the Empire and whose production can be increased by cultivation (as for instance, in India and Burma, which all who have studied the subject must admit) sufficient for the Empire's requirements, the use of valuable coniferous woods for this purpose, is to be deplored. The trees that are being cut up and so manufactured not only in British Columbia, but in Newfoundland (where the paper making industry from soft wood is even larger) have taken over a century to grow, whereas grasses (excluding bamboos) and shrubs are producible in a year or two or three at the most. In seconding the vote of thanks to the reader of the paper on the subject of paper manufacture last year at a meeting of the Indian Section of the Royal Society of Arts, I mentioned that in India there exist untapped sources of wealth from fibres and grasses for paper manufacture, which ought to be developed. If efforts within the Empire in this and other directions were co-ordinated, which I take the liberty to suggest may be one of the first duties of the Empire Forestry Association, the wasteful sylvicultural methods in British Columbia so vigorously condemned by Sir David Prain, would probably cease.

OBITUARY.

SIR FREDERIC W. R. FRYER, K.C.S.I.—By the death, on February 20th, of Sir Frederic William Richards Fryer, late Lieutenant-Governor of Burma, the Indian Committee of the Royal Society of Arts loses a useful and valued Fellow. Shortly after his retirement from the Indian Civil Service nearly two decades ago he read before the Society an admirable and comprehensive paper on Burma. At that time much was being heard of a demand for making Burma a Crown colony by uniting her to Ceylon and the Straits Settlements. Sir Frederic Fryer gave numerous reasons for his strong opinion that the province would really suffer instead of gaining by ceasing to be administratively part of the Indian Empire, even though constituted a separate Crown colony, nor could he see that it would be advantageous to her to be linked to the Straits Settlements or Ceylon.

He joined the Society in 1907 and in the same year was elected a member of the Indian Committee. Throughout his long connection with the Society he seldom missed an Indian meeting, taking the chair on more than one occasion

and frequently contributing to the discussions.

Born in 1845 he was the son of Mr. F. W. Fryer, of West Moors, Dorset, and received his education abroad as well as at the Bromsgrove Grammar School founded by Edward VI. A successful competitor in the Indian Civil Service Examination of 1863 he was posted in 1864 to the Punjab, where he acquired the reputation of an able and active frontier officer. He was transferred to Burma in 1886 for the purpose of assisting in the pacification of the territory annexed on the overthrow of King Theebaw and his services in that capacity marked him out for promotion. In 1895 he was appointed Chief Commissioner and in 1897 he became the first Lieutenant-Governor of Burma, retiring in 1903. Consequently he was head of the Administration for no less than eight years, a very unusual experience. He was created a Knight Commander of the Star of India in 1895 while officiating as Financial Commissioner of the Punjab and occupying a seat in the Viceregal Legislative Council as an "additional member."

WILLIAM J. STARR, B.A., LL.B.—Mr. William J. Starr of Eau Claire, Wisconsin, and Easton, Maryland, U.S.A., died suddenly on December 13th, 1921. He was elected a Fellow of the Royal Society of Arts, in 1916. A graduate of Harvard University, Mr. Starr was generally known as one of the leading naval architects in the United States but in addition to this he was a naturalist and an authority on trees and woods, and also a founder of libraries and a promoter of institutions of art and learning. Mr. Starr's business undertakings were varied and extensive. At the time of his death, he was President of two large manufacturing enterprises in Wisconsin. He was the founder and president of a large orchard company and stock farm. He owned large tracts of timber land in California and swamp land, which was under the process of reclamation, in Louisiana. During his life he reclaimed over sixty-thousand acres of land in northern Wisconsin and it was largely through his efforts that Wisconsin now heads the list as a dairy state. Mr. Starr lived upon a colonial estate in Maryland whose original land grant was made by Lord Baltimore in 1666. He was a distinguished member of many scientific societies and organisations, including the Committee of One Hundred for the Beautifying of Washington, The Deeper Waterways Commission, the Academy of Political Science, the Wisconsin Historical Society, the Sons of Colonial Wars. He was also a member of the New York Yacht Club, vice-commander of the Chesapeake Bay Yacht Club, and a member of the Salmagundi Club, New York and Union League Club, Chicago.

NOTES ON BOOKS.

THE TIMES OF INDIA ANNUAL, 1922. Bombay : The Times Press, Rs. 2.

This beautifully got-up Annual affords striking evidence of the remarkable advance in printing that has taken place in India in recent years, and shows what fine work a well-equipped and properly organised press in that country is now able to accomplish. Pictorially and otherwise, the volume has been connected with the Royal visit, and the place of honour is given to an ode by Sir William Watson to the *Heir Apparent* :—

"Guest of this ocean-seated, mountain-crowned
Mother of half Earth's tongues"

Especially attractive are the numerous contributions, in pen as well as in pencil, of an old pupil of the late Sir Hubert Heikomer, R.A., Mr. Cecil L. Burns, ex-Principal of the Bombay School of Art, one of whose articles deals with "Indian Memorials in London Byways." An interesting account of the renaissance of Indian music is given by the Principal of the Baroda school of music, and the varied contents also include a story entitled "Two Terrors," by George Birmingham. The addition of a list of contents would have been an improvement.

THE MANUFACTURE OF STRINGED INSTRUMENTS AT NAGOYA.

Although stringed instruments adapted to European use were made in Japan in some quantity before the war, the enforced withdrawal of German competition abroad created an instant demand to which the Japanese manufacturer promptly responded, and though the export industry is of comparatively recent growth it has already assumed considerable proportions.

From a report by the U.S. Consul at Nagoya, it appears that almost all of the stringed instruments exported, and the greater number of those of superior quality sold in Japan, are the product of one Nagoya house founded by Mr. Masakichi Suzuki, who in 1888 made his first violin, using as a model a foreign instrument brought to Nagoya as a curiosity. As a result of study and experiment the best grades of instruments now produced are said to bear favourable comparison with those of German make, whose place they have entirely taken in domestic and very largely in foreign (especially American) trade.

The basic materials employed in making the instruments are Japanese maple and pine, which have been found admirably suited to this purpose. Other materials which it has been found necessary to import are fine hardwoods, such as Pernambuco wood, rosewood, mahogany, and ebony, from Brazil and India; ivory, also from India; horsehair from China, and sheep gut, principally from Australia.

Mr. Suzuki claims especial excellence for the finish of his instruments, which he attributes to the use of an oil varnish instead of the alcoholic varnish commonly applied. There are three Suzuki factories now in operation in Nagoya, with 1,100 employees.

In 1913, the year preceding the war, the total value of instruments and accessories produced was only about £5,000, of which about 8 per cent entered into the export trade; while in 1919 the value of production was about £108,000, of which almost 74 per cent. represents exports. Nearly 68 per cent. of the exports went to the United States. For the first six months of 1920 musical instruments to the value of about £61,000 were produced.

Mr. Suzuki believes that the Germans cannot manufacture instruments at Japanese costs, and that the instruments of Japanese manufacture having proved their good quality, in spite of prejudices which were at first entertained abroad, have now established themselves so firmly in foreign markets, and especially in the United States, that they cannot be displaced.

HAT INDUSTRY IN ARGENTINA.

There are 8 large factories and about 15 small shops in Buenos Aires devoted to the production of soft and stiff hats. The largest of these establishments employs between 200 and 300 persons, depending upon the season; the three next in size employ approximately 100 each, while the remainder have about 50 persons as a minimum.

All operations are performed by each establishment, the larger ones even doing a part of their own cleaning, carotting, and cutting. The principal raw material used is hatters' fur, and the skins are mostly those of the native winter hare. Rabbit skins are employed to a limited extent, but nutria, castor, and other furs are seldom touched. There are also independent fur cutters, whose product is not high grade, and therefore has little demand, except for mixing with better fur to produce a cheaper hat.

According to a report by the United States Trade Commission in Argentina, previous to 1914, very little hatters' fur was actually prepared within the country, it having been more economical and generally satisfactory to import the blends or types required from Europe and the United States. The experience of the last few years has proved that the fur can be produced quite well at home, and it is therefore likely that the industry will continue. Although the greater part of the fur is brought in, the total requirements can only be approximated, since no accurate statistics are available regarding either the amount imported, the amount prepared locally, or the number of hats turned out. Estimates of the latter place the total output at 110,000 to 125,000 dozens yearly.

Each hat requires from 110 to 115 grammes of fur. One of the large manufacturers carries on hand a stock of 14 to 15 tons of blown fur. In this quantity are represented many kinds of furs, but ordinarily any of the standard mixtures or types are satisfactory.

Hardening and sizing are carried on by hand or machinery, according to the type or quality of the finished hat. These machines, as well as the blowers and forming machines, are usually of English make. Machines for other purposes are brought from Italy, the United States, or whichever country happens to be foremost in a particular line, the larger factories being quite as well equipped as the average establishments in any other part of the world.

The goods turned out are of excellent quality, except in those cases where low-grade hats are made intentionally.

Sweat bands are made by several small shops, but on account of their poor quality are used only for the cheaper hats. The British makes are the most popular of the imported bands, some 75 per cent. coming from England as against 22 per cent. from the United States. The market is not confined to the fur felt hat factories, but embraces also the manufacturers of straw hats, cloth hats, caps, and military and police helmets. Silk bands, ribbons and lining materials come from France and Italy. Other accessories, such as sewing thread, sandpaper for pouncing, dyes and shellac are usually purchased in the open market.

GENERAL NOTES.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Mr. Thomas E. Collcutt, Past President of the Royal Institute of British Architects, has organised a competition for young architects and architectural students, who are to prepare designs for a business building facing on an ordinary London street, in which "colour" of a permanent nature is to be the dominant feature. The judges in the competition will be Mr. Collcutt himself, Sir Edwin Lutyens, R.A., and Professor Gerald Moira, of the Royal College of Arts. The sum of £200 has been handed to the President of the Royal Institute of British Architects by an anonymous donor to provide prizes for this competition. The first prize will be £100, and there will be other prizes of £50, £30 and £20. The designs submitted will be exhibited at the Royal Institute after the close of the competition.

INDIAN TIMBERS AND PAPER MATERIALS.—Enquiries into the possibility of increasing the utilisation of Indian timbers in this country and of making use of Indian paper materials have been carried out in connection with the Indian Trade Enquiry undertaken by the Committee for India of the Imperial Institute,

and the reports have just appeared in a volume published by Mr. John Murray under the title "Reports on Timbers and Paper Materials" (price 4s.). Hitherto the exports of timber (other than teak) from India have been relatively small, owing chiefly to the existence of a large local demand. It is considered, however, that there would be an opening for an extended export trade to the United Kingdom in certain hardwoods, which would be of value for decorative and other purposes, and are at present little known in this country. The characters and uses of a number of such timbers are described. In the section on paper materials, a general statement is given as to the world's pulp and paper-making industry, special reference being made to the position in India. Details are included as to the possibility of utilising Indian bamboos and savannah grasses for paper-making, and the opinion is expressed that in these two materials India possesses valuable resources which occur under circumstances not unfavourable for their commercial development. It is considered that the immediate aim in the developments of an Indian paper-pulp industry, which should receive every encouragement from the Government of India, should be to reduce, and finally replace (as far as possible) by Indian supplies, the large amount of pulp and paper imported into that country. It is believed that the replacement of imports by Indian produce would be quickly followed by a surplus production which would be available for export.

CINNAMON.—The current number of the *Bulletin* of the Imperial Institute contains an article on cinnamon, its sources, production and trade, giving a detailed account of the production of the bark in different parts of the Empire, as well as in foreign countries, and a description of the aromatic oils yielded by cinnamon and related trees. The finest cinnamon bark is produced in Ceylon, where the Portuguese found the tree growing wild when they arrived in the island in 1505. Since that date Ceylon has been famed for this spice, but owing to the small financial return it gives to the growers, much of the area under cinnamon in the island has been replaced by the more profitable coconut and Para rubber. Ceylon cinnamon, moreover, has had to compete, particularly in the Continental markets, with a cheaper product of coarser flavour from the Far East. Cinnamon bark reaches this country in two forms: the ordinary "quills," used as spice, and "chips," which are distilled for the production of cinnamon oil used in medicine. The leaves of the cinnamon tree yield an entirely different oil from that of the bark: this oil contains eugenol (the characteristic constituent of oil of cloves) which is employed in the manufacture of vanillin, the well-known flavouring agent. Cinnamon leaf oil is produced largely in the Seychelles.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, MARCH 6. People's League of Health, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Sir Robert Armstrong Jones, "Fatigue and Sleep."

Farmers' Club, at the Surveyors' Institution, 12, Great George Street, S.W., 4 p.m. Prof. W. Somerville, "The Improvement of Poor Pasture."

Royal Institution, Albemarle Street, W., 5 p.m. General Monthly Meeting.

Geographical Society, 131, New Bond Street, W., 8.30 p.m.

Surveyors' Institution, 12, Great George Street, S.W., 8 p.m.

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. Mr. W. Cullen, "Gold Metallurgy of the Witwatersrand, Transvaal."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Informal Meeting.) Mr. E. Ambrose, "E.H.T. Cable Testing." (Western Centre), Merchant Venturers' Technical College, Bristol, 6.30 p.m. Mr. L. H. A. Carr, "Induction-Type Synchronous Motors."

TUESDAY, MARCH 7. Royal Institution, Albemarle Street, W., 3 p.m. Sir Arthur Keith, "Anthropology of the British Empire (Lecture III)." Royal United Service Institution, Whitehall, S.W., 3 p.m. Anniversary Meeting.

Anglo-French Society, Scala House, Tottenham Street, W., 6.15 p.m. M. M. Thiers, "Le Théâtre de Meilhac et Halévy."

Alpine Club, 23, Savile Row, W., 8.30 p.m.

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. C. W. Milne, "On the Trail in Mexico."

Electrical Engineers, Institution of (E Midland Centre), Technical College, Derby, 7 p.m. Mr. J. E. Driver, "The X-Ray Examination of Materials." (N. Western Centre), College of Technology, Manchester, 7 p.m. Dr. C. C. Garrard and Mr. F. Gill, "Exhibition of Cinematograph Films."

University of London, Royal School of Mines, Imperial College, South Kensington, S.W., 5.30 p.m. Colonel N. T. Belaislaw, "The Crystallization of Metals." (Lecture III.) At the London School of Economics, Houghton Street, Aldwych, W.C., 6 p.m. Sir Josiah Stamp, "The Administrative Factor in Government." (Lecture IV.)

Photographic Society, 35, Russell Square, W.C., 7 p.m. Scientific and Technical Meeting.

WEDNESDAY, MARCH 8. Royal Society for the Prevention of Cruelty to Animals, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Major-General Sir L. J. Blenkinsop, "The Problem of Horse Traffic on Modern Road Surfaces."

Royal United Service Institution, Whitehall, S.W., 3 p.m. Colonel W. M. St. G. Kirke, "The Development of Communications in the Middle East and their Strategic Importance."

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's Gate, S.W. (Morning Session, 10 a.m. to 1 p.m.) (1) Annual General Meeting. (2) Dr. G. D. Bengough, "Notes on the Corrosion and Protection of Condenser Tubes." (Afternoon Session, 2.30 p.m. to 4.30 p.m.) (1) Mr. F. Adcock, "The Internal Mechanism of Cold-Work and Recrystallization in Cupro-Nickel." (2) Major C. J. Smithells, "The Effect of Impurities on Recrystallization and Grain Growth." (3) Messrs. H. Moore and S. Beckinsale, "Further Studies in Season-Tracking and its Prevention. Condenser Tubes."

University of London, King's College, Strand, W.C., 5.15 p.m. Prof. Nils Bohr, "The Quantum Theory of Radiation and the Constitution of the Atom." (Lecture I.) At the London School of Medicine for Women, Hunter Street, W.C., 5 p.m. Dr. H. H. Dale, "Some Recent Developments in Pharmacology." (Lecture III.)

Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Sheikh Abdel Razek, "The Mosques of Cairo."

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m. Professorial Lecture.

Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Miss B. Voysey, "The Personal Factor in Industry."

Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Prof. S. L. Cummins, "The Clinical Differences in the Course of Tuberculosis seen in various Age Groups and Races."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. Mr. A. A. Remington, "The Design and Function of Laminated Automobile Suspension Springs."

THURSDAY, MARCH 9. Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. L. F. Newman, "The Low Temperature Research Station at Cambridge."

Royal Society, Burlington House, Piccadilly, W., 4 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Historical Society, 22, Russell Square, W.C., 5 p.m. Miss G. Whale, "The Influence of the Industrial Revolution (1760-1790) on the Demand for Parliamentary Reform."

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Miss Combs and Mrs. Bottrill, "The Family Group System in Infant Schools."

Optical Society, Imperial College of Science, South Kensington, S.W., 7.30 p.m.

Central Asian Society, at the Royal United Service Institution, Whitehall, S.W., 5 p.m. Air-Commodore H. R. M. Brooke-Popham, "Some Notes on Aeroplanes, with special Reference to the Cross Desert Route from Calcutta to Baghdad."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. H. M. Letov, "Insect Pest Control." (Lecture II.)

Anglo-French Society, Scala House, Tottenham Street, W., 6.15 p.m. M. Emile Cammaerts, "La poésie moderne de la langue Française." (Part I.)

Faraday Society and the Oil and Colour Chemists Association (Joint Meeting), at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. Metals, Institute of, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 10 a.m. Annual Meeting continued (1) Prof. C. A. Edwards and Mr. A. J. Murphy, "The Rate of Combination of Copper and Phosphorus at Various Temperatures." (2) Dr. W. Rosenhahn, Note on "Some Cases of Failure in Aluminum Alloys." (3) Prof. F. C. Thompson and Mr. E. Whitehead, "Some Mechanical Properties of the Nickel-Silvers." (4) Dr. D. Hanson and Marie L. V. Gayler, "A Further Study of the Alloys of Aluminum and Zinc." (5) Mr. A. Westwood, "The Assay of Gold Bullion."

Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Dr. L. D. Barnett, "The Hindu Culture of India." (Lecture II.)

Dyers and Colourists, Society of (Bradford Junior Branch), Mr. H. Winslow, "The Franklin Dyeing Process."

FRIDAY, MARCH 10. London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 4.30 p.m. Captain L. Thompson, "The Open Air Life of London."

Royal Institution, Albemarle Street, W., 9 p.m. Prof. T. R. Merton, "The Variability of Spectra."

Metals, Institute of, at the Sir J. Cass Technical Institute, Jewry Street, E.C., 8 p.m. Dr. D. Hanson, "Micro-structure and Physical Properties of Alloys."

Astronomical Society, Burlington House, Piccadilly, W., 5 p.m.

Malacological Society, at the Linnean Society, Burlington House, Piccadilly, W.

Physical Society, at the Imperial College of Science, South Kensington, S.W., 5 p.m.

Electrical Engineers, Institution of (Irish Centre), Royal College of Science, Dublin, 8 p.m. Prof. R. Stanley, "Wireless Communication in the Campaign in France."

SATURDAY, MARCH 11. Royal Institution, Albemarle Street, W., 3 p.m. Sir Ernest Rutherford, "Radio-Activity." (Lecture II.)

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday of the week preceding the Meeting.

Journal of the Royal Society of Arts.

No. 3,616

VOL. LXX.

FRIDAY, MARCH 10, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 15th, at 8 p.m.
(Ordinary Meeting.) OSWALD T. FALK,
"Certain Aspects of the Problem of Exchange
Stabilisation." SIR ROBERT M. KINDER-
SLEY, K.B.E., in the Chair.

FOURTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 1st, 1922; Mr.
Percy A. Scholes, Music Critic to the *Observer*,
in the Chair.

The following candidates were proposed
for election as Fellows of the Society:

Donald, Bernard Speirs, London.

Seago, Miss Muriel, Harrogate

The following candidate was balloted for
and duly elected a Fellow of the Society:-
Armstrong, Frederick William, Manchester.

A paper on "The Duplex Coupler
Pianoforte" was read by Mr. Emanuel
Moor.

The paper and discussion will be published
in a subsequent number of the *Journal*.

CANTOR LECTURE.

On Monday evening, March 6th, PRO-
FESSOR ALAN F. C. POLLARD, F.Inst.P.,
A.M.I.E.E., delivered the third and final
lecture of his course on "The Mechanical
Design of Scientific Instruments."

On the motion of the Chairman, SIR
HERBERT JACKSON, K.B.E., F.R.S., a vote
of thanks was accorded to Professor Pollard
for his interesting course.

The lectures will be published in the
Journal during the summer recess.

THE ALBERT MEDAL.

The Council will proceed to consider the
award of the Albert Medal of the Royal
Society of Arts for 1922 early in May next,
and they therefore invite Fellows of the

Society to forward to the Secretary on or
before Saturday, March 25th, the names of
such men of high distinction as they may
think worthy of this honour. The medal
was struck to reward "distinguished merit
in promoting Arts, Manufactures, and
Commerce," and has been awarded as follows
in previous years:—

1864, Sir Rowland Hill, K.C.B., F.R.S.

1865, His Imperial Majesty, Napoleon III.

1866, Michael Faraday, D.C.L., F.R.S.

1867, Sir W. Fothergill Cooke and Sir Charles
Wheatstone, F.R.S.

1868, Sir Joseph Whitworth, LL.D., F.R.S.

1869, Baron Justus von Liebig.

1870, Vicomte Ferdinand de Lesseps, Hon.
G.C.S.I.

1871, Sir Henry Cole, K.C.B.

1872, Sir Henry Bessemer, F.R.S.

1873, Michel Eugène Chevreul, For Memb.
R.S.

1874, Sir C. W. Siemens, D.C.L., F.R.S.

1875, Michel Chevalier

1876, Sir George B. Airy, K.C.B., F.R.S.

1877, Jean Baptiste Dumas, For. Memb. R.S.

1878, Sir Wm. G. Armstrong (afterwards Lord
Armstrong), C.B., D.C.L., F.R.S.

1879, Sir William Thomson (afterwards Lord
Kelvin), O.M., LL.D., D.C.L., F.R.S.

1880, James Prescott Joule, LL.D., D.C.L.,
F.R.S.

1881, Professor August Wilhelm Hofmann,
M.D., LL.D., F.R.S.

1882, Louis Pasteur.

1883, Sir Joseph Dalton Hooker, K.C.S.I.,
C.B., M.D., D.C.L., LL.D., F.R.S.

1884, Captain James Buchanan Eads

1885, Sir Henry Doulton

1886, Samuel Cunliffe Eister (afterwards Lord
Masham).

1887, HER MAJESTY QUEEN VICTORIA.

1888, Professor Hermann Louis Helmholtz.

1889, John Percy, LL.D., F.R.S.

1890, Sir William Henry Perkin, F.R.S.

1891, Sir Frederick Abel, Bt., G.C.V.O.,
K.C.B., D.C.L., D.Sc., F.R.S.

1892, Thomas Alva Edison.

1893, Sir John Bennet Lawes, Bt., F.R.S., and
Sir Henry Gilbert, Ph.D., F.R.S.

- 1894, Sir Joseph (afterwards Lord) Lister, F.R.S.
 1895, Sir Isaac Lowthian Bell, Bt., F.R.S.
 1896, Professor David Edward Hughes, F.R.S.
 1897, George James Symons, F.R.S.
 1898, Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S.
 1899, Sir William Crookes, O.M., F.R.S.
 1900, Henry Wilde, F.R.S.
 1901, HIS MAJESTY KING EDWARD VII
 1902, Professor Alexander Graham Bell
 1903, Sir Charles Augustus Hartley, K.C.M.G.
 1904, Walter Crane
 1905, Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.
 1906, Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.
 1907, The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.
 1908, Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.
 1909, Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.
 1910, Madame Curie
 1911, The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., F.R.S.
 1912, The Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S.
 1913, HIS MAJESTY KING GEORGE V
 1914, Chevalier Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.
 1915, Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S.
 1916, Professor Elias Metchnikoff
 1917, Orville Wright
 1918, Sir Richard Tetley Glazebrook, C.B., Sc.D., F.R.S.
 1919, Sir Oliver Joseph Lodge, D.Sc., LL.D., F.R.S.
 1920, Professor Albert Abraham Michelson For Member, R.S.
 1921, Professor John Ambrose Fleming, D.Sc., F.R.S.

PROCEEDINGS OF THE SOCIETY.

ELEVENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 8TH, 1922.

Owing to the unavoidable absence of Sir ARTHUR DUCKHAM, the Chair was taken by Mr. W. J. U. WOOLCOCK, C.B.E., M.P.

The Paper read was:—

SOME SOLVED AND UNSOLVED PROBLEMS IN GAS WORKS CHEMISTRY.

By E. V. EVANS, F.I.C.

Having chosen so comprehensive a title for a short paper, it will be possible to select only a few of the many problems

which present, or have presented, themselves to the gas chemist, and this selection is made almost at random.

NAPHTHALENE.

It is the duty of a gas undertaking to supply to its consumers a gas reasonably constant in composition and uninterruptedly adequate in quantity. In order to carry out this requirement of adequacy of supply, it is necessary from time to time, as the business of the gas undertaking increases, to augment, up to a certain point, the pressure at which the gas is supplied, or to relay the mains and services which have become incapable of dealing with the increased volume of gas. This is a question for the engineer. Gas engineers have been much harassed in the past by naphthalene, which separates out in a solid form from coal gas and reduces the carrying capacity of the mains and services. This is a question for the chemist, who is hardly justified in studying the more interesting questions of the retort house or of the efficiency of gas appliances, if the gas manufactured cannot, without interruption, be relied upon to reach the consumer's appliances owing to naphthalene stoppage. The naphthalene problem does not to-day fall under the category of the unsolved.

Before proceeding to describe one method which it is suggested solves the naphthalene problem, it is unfortunately necessary to emphasise the fact that gas technologists have been led astray in the past as a result of relying upon certain naphthalene vapour pressure determinations made by Allen in 1900. From his determinations it would be inferred that wet coal gas at the freezing point of water is saturated by six grains of naphthalene per 100 cu. ft.; but recent investigation by Dr. J. S. G. Thomas has shown that this is incorrect, and that saturation is attained with only 0.8 grains of naphthalene per 100 cu. ft. (Fig. 1.) The original investigator's curve is correct for temperatures above about 90° F., but his results are misleading over the temperature interval, which is of the greatest interest to gas engineers. These determinations of vapour pressure refer to the weight of naphthalene that saturates the gas under varying conditions of temperature, and are made by ascertaining the weight of naphthalene existing as vapour when gas is in contact with an excess of solid naphthalene. It does not follow that

FIG. 1.

the gas is incapable, under certain conditions, of retaining as naphthalene vapour quantities greater than those indicated by the curve. This aspect of the question, which is a highly complex one, has not been studied; the deposition of naphthalene is influenced by the state of motion of the gas, the rate of change of temperature and probably also by the nature of other hydrocarbons present. Owing to the absence of precise knowledge of the conditions which govern the deposition of naphthalene from coal gas, the question has been referred to as the "Naphthalene Bogey," and would frequently seem to be regarded as phenomenal. Naphthalene deposition is indeed so complex that there exists a school of gas technologists who believe that, to gain perfect immunity from annoyance, all naphthalene should be extracted from the gas before it leaves the works for distribution. By complete

extraction of naphthalene is meant that the gas passed through an aqueous solution of picric acid at the rate of 1 cu. ft. per hour for 24 hours gives no precipitate, or perhaps so little that it is unweighable on an ordinary chemical balance.

Now, ordinary anthracene or heavy oil resulting from the distillation of coal tar is an efficient solvent for naphthalene; but the oil, as ordinarily distilled, itself contains naphthalene and is thus unsuitable for the complete extraction of this hydrocarbon from gas. If, for example, air be drawn through a sample of anthracene oil, it will be seen that a copious precipitate is obtained by washing that air subsequently with an aqueous solution of picric acid. (Experiment). Bueb, in Germany used this medium for naphthalene washing in 1902, but the washed gas contained from 3 to 4 grains of naphthalene per 100 cu. ft., and reference to the vapour pressure curve will

FIG. 2

show that this quantity represents the saturation point of wet gas at 13°C. (55°F.). If, however, the oil be steam distilled before use and then applied systematically to the gas stream in a compartment washer-scrubber, the complete extraction of naphthalene may be effected. Now, an equal quantity of air to that used in the previous experiment, when drawn through steam distilled oil is seen to give no precipitate with aqueous picric acid. (Experiment). This oil is used in a washer-scrubber of 10 bays (Fig. 2) and flows in counter direction to the gas at the rate of about about 15 gallons per million cu. ft. of gas. The spent oil flowing from the final bay possesses a concentration of 6 to 8% of naphthalene and the concentration decreases in each bay until in the oil inlet bay it is practically free from naphthalene. (Fig. 2). The amount of oil used is that required to remove completely the naphthalene from the gas; and the figure quoted above is an average one. The cost of operating the process is shown in Fig. 3.

WORKING COSTS OF NAPHTHALENE EXTRACTION.

Item.	Per 1000 c. ft.	Per 10 Therms.
	Pence.	Pence.
Oil used... ..	.1059	.189
Wages0105	.019

Repairs and maintenance and sundries0044	.008
	.1404	.251
Interest on capital0285	.051
Establishment charges...	.0122	.022
	.1811	.324

FIG. 3.

This process in the case of the South Metropolitan Gas Company, extracts about 130 tons of naphthalene annually. The effect upon the business of a gas undertaking is shown by the curve in Fig. 4, which represents the decrease in the total annual number of naphthalene complaints received from consumers during the last few years. This diagram is given solely to demonstrate the slope of the curve, which is a *bona fide* one; numerical values are

FIG. 4.

not given. Although the attainment of 1921 is not far from the zero line, it may still be some little while before this ideal, representing complete freedom from naphthalene complaints is reached, as there must still exist some naphthalene left in the smaller and less used services as a heritage of former years.

SULPHUR COMPOUNDS.

It is not proposed to deal at any length with the subject of the removal of sulphur compounds from gas. It is, however, of interest to state that Dr. Carpenter has, within recent times, considerably improved and simplified the nickel catalytic process; and it is to be hoped that he will communicate to the gas industry the nature of this work when it is completed.

Upon the subject of carbon bisulphide, one observation has recently been made which is particularly suitable for lecture demonstration. An enquiry into the causes which determine the fluctuation of the flow of gas and consequent unreliability of certain bypass tubes adjacent to the inverted incandescent burner, showed that the gas flowing through the bypass tube during the lighting period of the burner is raised to such a temperature that there exists within the tube a miniature sulphur removal process. The conditions are here

reproduced [Experiment] whereby it is seen that gas, after passing through a heated byepass tube adjacent to an inverted burner, contains hydrogen sulphide, as shown by the brown colouration of lead acetate paper. A control burner carrying an unimpregnated paper shows a negative result. In the heated byepass tube, carbon bisulphide in the gas is undergoing decomposition with the production of hydrogen sulphide and the deposition of carbon; and this deposited carbon, together with the metallic sulphide produced, is one of the contributing factors to the inefficiency of this form of byepass. The difficulty may be overcome by designing the burner and byepass in such a way that the latter does not become heated, or by making that portion of the tube liable to be heated of pipe clay or other suitable insulating material.

HYDROGEN SULPHIDE.

The method of removing hydrogen sulphide from coal gas by means of oxide of iron, though almost universally practised to-day by gas undertakings, is an ancient process. The chemist has been unable to recommend an alternative, so trustworthy and economical, as to render the present obsolete. In the ideal process the value of the recovered sulphur or sulphuric acid should be at least equal to, if not greater than, the cost of operating the process. It is one thing to create an ideal and another to accomplish it, and it is believed that this problem still falls under the category of the unsolved. The present method is not only a financial burden to the gas undertakings, but it is also open to criticism in other respects. The physics of the process is unsound in that a gaseous impurity at an initial concentration of 1 per cent. by volume is extracted by means of a solid reagent. Again, the expenditure involved in handling large masses of solid oxide of iron in times of high labour costs accentuates the advantages that must accrue by discovering a simple process based on the use of a liquid reagent. Further, the presence of small quantities of hydrogen cyanide in the gas results in the formation of ferrocyanides which renders a proportion of the iron inactive during each cycle, and leads to the oxide becoming prematurely inactive. Finally, the efficiency of the oxide depends to a large extent on its physical nature and its selection is a matter of considerable importance.

To avoid excessive labour costs due to the handling of large masses of solid material and to allow of the selection of a rapid yet simple reaction uninfluenced by other constituents of the gas, the tendency in recent years has been to develop a wet method of purification in which solutions or suspensions may be dealt with by pumping machinery.

The fundamental reaction upon which by far the majority of the purification processes invented are based is that of the oxidation of hydrogen sulphide to water and sulphur.

This is indeed the resultant reaction of the iron oxide process, the hydrated ferric oxide merely acting as an intermediary which reacts with the hydrogen sulphide in the gas and is regenerated by contact with air, either in situ or externally. In viewing the reaction from this aspect and knowing also the ease with which hydrogen sulphide combines with oxygen, it is natural that the first attempt to discover a simple process would lie in the direction of endeavouring to oxidise the hydrogen sulphide in the coal gas mixture by a process of preferential combustion. Thus the experimental work would consist in conducting coal gas, firstly, over oxidising materials, which, at slightly elevated temperatures, would effect this reaction, or adding to the gas such a proportion of air or oxygen and then passing the mixture over a contact or catalytic substance, again at slightly elevated temperature, to promote the preferential combustion of hydrogen sulphide to sulphur and water vapour. If this reaction could have been induced to proceed satisfactorily it would not have been a difficult matter to remove the condensed sulphur by means of either filtration or electrical precipitation. A careful study of the properties of a large number of oxides was made but attempts to oxidise preferentially the hydrogen sulphide of coal gas, either by heated oxides or by the addition of air in the presence of a contact material or catalyst have been unsuccessful. In the first place, it is most difficult to prevent the oxidation of certain other constituents of the coal gas mixture; but the outstanding difficulty lies in the fact that a secondary reaction takes place when coal gas containing hydrogen sulphide is heated. Carbon oxysulphide resulting from the interaction of carbon monoxide and sulphur is the main

product of this side reaction. It escapes easily from the reaction zone and is a sulphurous compound more difficult to remove than hydrogen sulphide. It serves no good purpose to describe in any detail partly finished experimental work which has given negative results. Although finality is not reached, from the evidence at present acquired it would appear that a satisfactory solution of the problem is not to be found upon these lines. It is interesting to note that, in patents recently taken by Bayer & Co., and others, this reaction of the oxidation of hydrogen sulphide is caused to take place by means of contact of the gas with highly porous material such as charcoal. After such treatment, however, very few illuminants remain in the gas mixture, and, although these may probably be recovered at a reasonable cost, such a treatment is a very drastic one.

A more hopeful line of investigation for the solution of this problem would appear to lie in the use of oxidants in the cold, as not only is the cost of heating the gas avoided but the secondary reaction referred to above is obviated. The ideal oxidant should give on reduction by means of hydrogen sulphide in the gas a soluble product capable of easy regeneration to the original compound by the passage of air through the solution. The sulphur would then be the only material remaining out of solution and could be filtered off in a practically pure state. A fairly complete study has recently been made of inorganic and organic oxidants. It is only possible at this stage to demonstrate a typical organic reaction which has recently been protected by patent. It is well known that certain dyestuffs are readily reduced to colourless or faintly coloured products known generally as leuco-compounds which, in turn, are easily re-oxidised to the parent dyestuff. Indigo, for example, is insoluble but gives a soluble reduction product (indigo white). The dye is fixed upon the fibre by immersion of the fabric in the soluble leuco-compound, and then by subsequent exposure of the fabric to air, the fast colour is produced. It was found that hydrogen sulphide of gas is capable of effecting the reduction of certain dyestuffs which, in turn, re-oxidise to the original dyestuff by the passage of a current of air. The sulphur naturally remained out of solution. Investigations were made to discover those

dyes which are both soluble themselves and have soluble leuco-compounds so as to obtain the ideal type of oxidant. (Soluble dyes forming insoluble leuco-compounds can be used, but their reduction products require a large and unreasonable excess of air for their oxidation.) Unfortunately, few dyes of the required type could be found.

The reduction of such dyes by hydrogen sulphide in neutral solution proceeds, if at all, only very slowly, and consequently an accelerator has to be used in the form of some basic substance. Alkali carbonates and bicarbonates are very effective for this purpose, but, unfortunately, so much sulphur is lost owing to the formation of salts of polythionic acids, that the use of such compounds is prohibitive. Turning to the organic bases as accelerators, pyridine and allied compounds are found to give the best results since other types frequently undergo gradual oxidation during the aeration process, with consequent conversion to inactive substances. Pyridine is especially suitable since pyridine water mixtures act as solvents for certain leuco-compounds otherwise insoluble in water, e.g., leuco-methylene blue. The use of this solvent allows therefore a wider choice of dyestuffs. With such an organic base as promoter no loss of sulphur occurs; but unfortunately pyridine, owing to its high volatility, cannot be used in the gas stream without also installing a recovery plant. Higher boiling basic coal tar fractions of the quino-line series may also be used; but these necessary refinements materially alter the simplicity and financial aspect of the process, and, up to the present, interesting though the chemical aspect of these reactions may be, it has not been possible to recommend the abolition of oxide purification. Other processes that have from time to time been proposed for the displacement of oxide of iron do not present the simplicity of such oxidation reactions as those indicated above; and it is to be hoped that before long it will be possible to report success along these lines, effected either by inorganic or organic reagents. The indications of to-day are not unfavourable.

TOBACCO SMOKE.

Following a dissertation upon vat dyestuffs, it is thought that a diversion on tobacco smoke will be welcome. The aim and object of this diversion is to discuss

the question of risks. Statistics will show that by travelling to the Adelphi to-night each of us has incurred risk of death, that each day we risk death or accident by transit, ptomaines, food preservatives, disease and many other unwholesome things, including even a possible death from coal gas by carbon monoxide poisoning. To be alive is indeed to be subjected to a series of risks, but it is necessary, above all things, to maintain a due sense of proportion of such risks; and statistics will show that death by accidental gas poisoning constitutes an almost negligible risk to the community. Now, the chemist is unfortunately able to detect dangers that others fail to see. About 90 per cent. of our manhood smoke, and I propose to show you what risks are involved in this pleasant operation of smoking. [The Lecturer here lighted and smoked a cigarette.] Its risks are really negligible, the process of smoking having proceeded without any apparent harm since the days of Raleigh. Notwithstanding this, the chemist can scare the public, if he so wishes, on this question of smoking, and upon many others. Parliament has decreed that coal gas shall be free from hydrogen sulphide, and has instituted a severe test, in which the gas is passed over papers previously immersed in lead acetate solution. It will be seen that the lead paper in the cigarette holder has already turned brown, showing the presence of hydrogen sulphide, whilst the second control paper, not previously immersed in lead acetate solution, shows no colouration. (It may have been thought that the colouration was due to tarry matter deposited from the smoke.) Now, the quantity of hydrogen sulphide is exceedingly small, and the risk is probably negligible, yet the chemist has to remember that hydrogen sulphide which is undoubtedly drawn into the mouth when smoking, is appreciably more toxic than carbon monoxide, and in addition to this, is a cumulative poison. This, however, is not the sole toxic constituent of tobacco smoke; it may be demonstrated that carbon monoxide and hydrogen cyanide (prussic acid) are also present. There is here a small apparatus for producing tobacco smoke. The process of smoking is partly one of combustion, partly carbonisation, and the plant resembles a miniature gas works. A retort house of cigarettes leads to a condenser packed with glass wool for the purpose of

arresting tarry matter; the gases are then washed by an alkaline solution for the purpose of removing hydrogen sulphide and hydrogen cyanide, then by an acidified solution for the purpose of removing alkaline constituents of the smoke. The gases are then measured and are collected in the sample holder. The exhaustor is the gas holder, which has to be operated intermittently following the method of cigarette smoking. It is in this apparatus that some of the determinations have been made which allow of subsequent statements. The time taken in working this apparatus is too long for a lecture-demonstration, but in order to prove the presence of the toxic substances in tobacco smoke a Havana cigar is now being smoked through a purifying apparatus, which consists, firstly, of a wash bottle of caustic potash for the purpose of arresting hydrogen sulphide and hydrogen cyanide; secondly, of a loosely packed tower of soda-lime, and finally, through a solution of bullock's blood. It is shown, even after a short period of smoking the cigar, that both hydrogen sulphide and hydrocyanic acid are present in the caustic potash, whilst the characteristic change of colour in the blood solution is indicative of the presence of carbon monoxide. Tobacco smoke contains quite appreciable quantities of the toxic gas, carbon monoxide. It has been found, for example, that the smoke from a cigarette contains up to $1\frac{1}{2}$ per cent., whilst that from a cigar smoked irregularly contains up to 7 per cent. Assuming that carbon monoxide is not absorbed by the membranous coating of the mouth, it may be shown that with four people smoking cigars in one room the carbon monoxide contained in the air is liable to be equivalent to an escape of gas which would certainly be obvious to the olfactory organ.

During last year, a Committee appointed by the Board of Trade, under the Chairmanship of Sir William Pearce, reached the important conclusion that no limit should be placed upon the percentage of carbon monoxide to be contained in the gas distributed to the public. This Committee was fully alive to the toxicity of carbon monoxide, and to the responsibility it may be called upon to take by arriving at this decision, but it is suggested to you that to be read into its decision is its belief that the gas industry is now equipped with men of science at the University of Leeds,

South Kensington and other centres, and the safety of the public can be entrusted to the gas undertakings. The chemist will play an important role in deciding upon any change that, for economic reasons, may warrant an alteration in the constitution of the gas supplied. The Institution of Gas Engineers has shown itself to be fully capable of conducting, with the aid of the University of Leeds, careful and comprehensive investigations into matters affecting the fundamental principles of gas manufacture, and the public may rely upon such a body continuing to protect their interests on the question of carbon monoxide.

Reverting again to these demonstrations upon smoking, I should like to add that, personally, although an ardent smoker, I think that the habit is a dangerous one, and causes more harm than does coal gas. Notwithstanding the risks to which one is subjected when smoking, I do not propose to discontinue it—preferring the risks. Neither is it my object to start a press campaign to depopularise smoking. The example is chosen solely to demonstrate how simple it is for the chemist to elaborate upon the question of the unknown risks of life. Whilst we must not shut our eyes to the engineering and chemical disabilities which may arise from unduly increasing the carbon monoxide content of gas, yet I should like to take this opportunity of urging the press and the public to retain a sane and balanced conception on the question of risk.

SMOKELESS FUEL.

For many years the German dye industry has adopted the practice of manufacturing a colour of high purity—in some cases reaching 100 per cent. chemical purity—and before sale have slightly diluted their product with a harmless material. This practice is not resorted to for the purpose of defrauding the customer, but it allows a manufacturer to become assured that each delivery from the works shall be consistent as regards the quantity of colour contained in it. The dyer knows, and implicitly relies upon the fact, that each unit weight of material taken by him will have the same dyeing effect. If there is one thing above all others that the chemist attached to the chemical industry soon learns to appreciate, it is the necessity

of maintaining the output of a consistent product. The tar distiller supplying anthracene, naphthalene, carbolic acid, etc., for the chemical market, has to work to a well defined specification. Naphthalene, for example, to realise full market price, must have a setting point of 79.5° to 79.6°C. , and must, above all, have the appearance of the material here shown. If imperfectly purified before final distillation, it may destroy a batch of dye intermediates, and in this event, the tar distiller can but expect his material to fall into disrepute. The raw material of the tar distiller is highly heterogeneous and to obtain from it products of consistent quality, there must exist an outlet for the impurities. There are, indeed, certain fractions of coal tar marketed whose specifications are not so rigid as to prevent the admixture, within limits, of other tar products resulting from processes of purification. The tar distiller, however, uses whenever possible the less marketable materials as fuel under the stills or boilers.

The Sales Department of a chemical undertaking continue to urge their technical colleagues to produce—if possible without additional cost—an article, be it creosote, pitch, anthracene, sulphate of ammonia, etc., which shall, in competition with other similar products, establish its supremacy on the market by superiority in the particular quality for which it is required. Now it is useless to have attained superiority unless consistency of output may be maintained. A not unimportant duty of the chemist in the gas industry is to aid the gas engineer to produce from a heterogeneous material coal products—be they gas, coke, tar or ammoniacal liquor, of consistent quality. It is essential that the gas engineer give first attention to the main product, coal gas, and in this respect the author regrets that one of the clauses of the Parliamentary Bills which the gas industry joined in framing—namely, that relating to the limit imposed upon the variation of calorific value did not refer to variations above, as well as below the declared calorific value—was not contained in the final Acts.

The next most important product of the gas works from the point of view of revenue, is coke, and it is to this product that chemists must turn their attention. Its purity must of necessity be dependent upon that of the original coal. In addition to this adequate care is not

always given to the cooling process. The method of dry cooling with the exclusion of air as practised by several gas works is ideal and it is hoped that such a method may be found capable of general application. Notwithstanding this the coke of to-day is a high-class industrial fuel and will demand even a more ready market than at present, and will probably bring a greater revenue to the gas undertakings in the future, if its manufacture is perfected. More attention should be given to the advisability of selecting, screening or washing the coal prior to its carbonisation, for the purpose of reducing the ash and sulphur of the resulting coke. This is no reason why, for industrial purposes, coke should not in the future entirely replace raw coal, and it is believed that the cost of reducing the ash content of coal prior to its carbonisation would be repaid by the saving of labour costs for clinking and the greater efficiency that may be obtained by the use in industry of coke so made. The opportunity may, however, be taken of describing to you a process recently worked out by E. R. Sutcliffe and Edgar C. Evans, whereby gas coal may yield a coke which is very suitable as an industrial fuel in that the ash from it falls away as a fine powder, completely free from combustible matter. [A sample of this ash, which is of a silky nature is shown.] In this process coal, admixed with a small quantity of breeze to prevent expansion during carbonisation, is ground to a fine state of division. It is then washed by a flotation process, dried and briquetted and subsequently carbonised. In the first place the briquettes are very dense and this, coupled with the reduction of ash, allows a greater throughput and larger output of gas and byproducts from existing plant. The coke retains approximately the form of the original briquette. [A specimen was shown.] It is not friable and is conveniently transported. Many claims are put forward by the inventors regarding the increased yields of distillation products, but the process has not yet been sufficiently examined by the author to allow of a critical discussion.

It is perhaps more particularly the problem of coke as a domestic solid fuel that should receive our attention. In the first place, it is assumed that, however efficient the gas fire and gas heating appliances in the future may be, there will remain a wide market for a good solid fuel.

Even if there is a doubt among gas technologists upon this question, there must be unanimity in the belief that raw coal should not be burned for industrial or for domestic use. Above all, coal, which is the basic raw material representing this country's main wealth, should not be exported in its raw state, but should be first treated, preferably at our gas manufacturing centres, for the manufacture of gas, motor fuels and raw materials for the chemical industry. It is not proposed to advocate to you the practice of low temperature carbonisation. Not only is the financial balance sheet of low temperature carbonisation less satisfactory than that of the manufacture of straight coal gas as practised to-day, but the great increase in the quantity of coal which would have to be carbonized, the difference in the nature of the products—particularly of the gas and the tar—the simultaneous creation of a market for the solid fuel, in addition to the disabilities surrounding the balance sheet, are all factors which cause the gas engineer to appear to be lethargic in this matter. It is not difficult to analyse the attitude of mind of the organic chemist on this question, but it is one thing to appreciate the attitude of mind, and another to revolutionize a stable industry when the financial advantages are certainly not apparent. This attitude of mind may be best explained by stating that the gas industry is one with which the organic chemist cannot be expected to be in immediate sympathy as its basic process is one of destructive distillation. The industry is indeed a poor training ground for the organic chemist who, after a long training during which he learns to handle and conserve organic molecules during a reaction in the laboratory (which means obtaining a high yield of the required product) is naturally shocked at the ruthless destruction of the coal constituents during high temperature carbonisation. It does not, however, take long for this discouragement to disappear, for he is rapidly made aware of the fact that high temperature gas production is a financially sound proposition.

The carbonisation of coal at low temperature is not in itself unsound, and it will probably be practised more largely in the future. Aiming at treating raw coal prior to its use, it constitutes a decided step towards the abatement of smoke, and the waste of valuable constituents of coal at home and the

conservation of such constituents in this country, if the solid fuel resulting from this process is that eventually to be exported. Solely from the point of view of smoke abatement, any solid fuel which may be burned with the ease of coal, and with as little trouble, will have a very ready market.

Now, the bye-product coke oven industry has sprung up in this country, and it is a question whether at least the major operations of this industry should not have been situated at gas works, for it is proved that the gas manufactured is quite suitable for a town's supply of gas. It should be at least admitted that the gas industry might have taken a more integral part in the building of this coke oven industry. The question now arises, are we about to permit a domestic fuel industry to be created and constitute itself as another coal distilling undertaking, marketing in competition to the gas industry solid fuel which will not only affect the use of coke for domestic purposes, but may even influence the output of gas for heating purposes. This is the problem that the gas works chemist will be expected to solve, and it is probable that he has already proceeded a long way in the direction of its solution. In an adjacent room there burns a fire of smokeless fuel, which has been made with gas coke as the basis; briquetting has not been used, neither is pitch the binding material, for this latter is not suitable for the manufacture of a smokeless fuel. The binding material is produced by the admixture of a proportion of cheap coal. The whole is heated to the temperature of the waste gases in the retort house. The process is a rapid one, as there is not much volatile matter to be driven away, but that which is driven away is recovered and has a definite market value. The volatile content of the resulting fuel is from 6 to 8 per cent. [A sample of the fuel is here shown.] It is not friable and is readily transportable. It ignites as readily as coal, and it is thought that it would be a material superior to coal were it not for the original ash in the coal and coke from which it is manufactured. On account of this domestic fires from this smokeless fuel are dirtier as regards ash than similar fires burning good household coal. When this question of ash is overcome, either by selection, screening or washing, it is then, I think, that we can be assured of possessing a material that will even be preferred to coal, and gas under-

takings will have made a further and, perhaps, a final contribution to the smoke abatement difficulty. The material burns to the silky-like ash described previously.

Much has already been written and said upon the advantages to be reaped by the abatement of smoke and it will be readily understood that gas undertakings will be one of the first to find immense advantage by the absence of solid particles in the air. The heritage that we possess in the gas industry by virtue not only of the efficiency of the gas making process, but also of the efficiency and economy of gas appliances, is one that is generally appreciated. The advantages of gas for heating and for power purposes are admitted by all who have adopted it. It is, however, in the production of light by the incandescent mantle that we are particularly fortunate. There exists in my opinion, no other means of artificial light which produces, on the one hand a soft light which is particularly suitable for the avoidance of eyestrain, and on the other a healthy circulation of air within the building or living room, and finally a degree of warmth which is an asset in all cases in eight months out of the twelve of each year, but which constitutes a very real convenience in the height of winter. Gas lighting is generally credited with the objection that our ceilings become blackened by it and more frequently require whitewashing. This is due to the fact that air, laden with solids, is driven at a high velocity in an upward direction by the ventilating effect of the burner, and then by the sudden reduction of this speed by contact with the ceiling a portion of the solid material is precipitated upon the ceiling. It is still believed by some that unburnt particles of carbon from the gas exist amongst the *mélange*, but this is untrue. With other forms of lighting there is no less solid matter in the air but without this ventilating effect such solid matter may find its way to the lungs of the occupant of the room. It is here possible to show slides which have been kindly loaned for this lecture by Dr. C. W. Saleeby, and demonstrate the lung of a town in contrast to that of a country dweller. (Figs. 5 and 6). Now it is a simple matter, and costs little, to cause our ceilings to be whitewashed but it is a task beyond even the manipulation of the surgeon of to-day to whitewash our lungs. Now there is a natural tendency in the human being to be more conscious

of the hole in the back of the sock above the shoe line than of one in the toe, and it must be admitted that, unlike the ceilings, our lungs are not open to the inspection of our friends and critics. There will come a time when it is considered as important to have a clean set of lungs as it is to-day to possess a set of sound and clean teeth. The gas engineer must realise that with a smokeless atmosphere gas lighting, secure though it is to-day, will have its one supposed disability removed.

In conclusion, my thanks are tendered to Dr. Charles Carpenter, whose ideas form the basis of our experimental work and whose

guidance is essential to any success that may have been attained. I should also like to take the opportunity of acknowledging my indebtedness to my assistants (Messrs. H. Hollings, M.Sc., H. Pickard, B.Sc., and H. Stamer, B.A.), and to the demonstrator of this evening, Mr. C. E. Carey, B.Sc.

[Figs 5 and 6 are reproduced by courtesy of the Editor of the *Gas Journal*.]

DISCUSSION.

THE CHAIRMAN (Mr. W. J. U. Woolcock, C.B.E., M.P.), in opening the discussion, said he was sure everyone present would agree that

the paper had been a most interesting one and had dealt with a great many different subjects. He thought he detected, underlying the artistry of the method of the author in presenting the paper, a certain amount of possibly contentious matter. His own reading had been more wide than thorough, but he certainly thought that at certain times he had come across differences of opinion on such subjects as carbon monoxide and smokeless fuel.

DR J. S. HALDANE, F.R.S., said he had listened with delight to the paper, which was full of interest from beginning to end, and he congratulated the Society on having obtained the services of the author to read such an interesting paper. As the Chairman had said, there were a great many controversial points dealt with by the author. Personally he proposed to deal with the last question discussed in the paper namely, the question of lungs. The author had painted a rather gruesome picture of the lungs of a town dweller and the lungs of a miner, and he wished to present the other side of the picture. He was pretty well acquainted with the subject, as he had had a great deal to do with it in one way or another for a very long time. The people in this country who breathed most coal dust were undoubtedly coal miners, but if the statistics of the deaths of coal miners from lung disease, particularly from consumption, were studied it would be found that such men were extraordinarily healthy. Among coal miners the death rate from consumption, which was commonly attributed to dust, was lower than it was amongst farm workers. That did not bear out the bad reputation which the inhalation of smoke particles had in popular opinion. He was not arguing that people should live in a smoky atmosphere: he was entirely in favour of having the air of London clear of smoke, first because the smoke made everything dirty and consequently made it more expensive to live in London and, secondly, because smoke obstructed the light and in that way caused much trouble, but he was very doubtful as to the effect the mere breathing of smoke particles had on the health of a man. When smoke particles went down into the lungs they were taken up by microscopical cells, and those living protoplasmic cells had the duty of cleaning up dust. They could be seen under the microscope crammed full of dust particles. After collecting those dust particles, they wandered up the air passages and came out. They were constantly carrying on that work of cleaning, and a person who lived in a pretty dusty atmosphere seemed to acquire a very efficient cleaning service on the part of those cells. During the time that a coal miner was working in the mine he always had what was known as a "black spit," which lasted for a considerable time after he had come out of the mine; it went on for weeks. That was good evidence that the

cleaning service of the man's lungs was doing its work well. The same cells had the duty of cleaning up micro-organisms, such as tubercle bacilli, which got into the lungs, and perhaps that was the reason why coal miners were so extraordinarily free from consumption. Fifty years ago the death rate amongst miners was very high, but there was very little phthisis. On the other hand, there were some kinds of dust that were deadly, one of those being quartz dust. For some reason or other, the cells of which he had been speaking were not capable of dealing with pure quartz dust. Many of the gold miners in the Transvaal contracted phthisis and died of it, and one of the most dangerous industries in this country, as Dr Collis had shown, was a very ancient one, i.e., the chipping of flints. Flint was a pure quartz and a small amount of flint dust which was breathed by the few men who still made flints caused them to be very subject to phthisis. The reason apparently was that the lungs were not accustomed to deal with out of the way chemicals like pure quartz dust; the quartz was totally insoluble and of no interest to the cleaning cells, so to speak. Ordinary wholesome dust was mixed with all kinds of things. Ordinary dust, for instance, made from earth was full of organic matter, which was just what the cells liked to have; they immediately took up that dust and walked out with it.

PROF. C. V. BOYS, F.R.S., said he agreed with Dr. Haldane that the paper had been a most interesting one, and it was quite obvious that everyone present was delighted with the very happy way in which the author had dealt with a number of subjects. He proposed to say a few words on the same question as Dr. Haldane had spoken upon and also to refer briefly to the subject of smokeless fuel. He had had something to do with the Minerals Separation Co. and their processes, which depended upon surface tension and not upon a mere washing operation. By this means certain minerals could be separated from others as froth, as was well known in the case of sulphide ores. They were now treating powdered coal to remove ash, i.e., such ash as is in the form of separate particles, not that inherent in the coal itself, and thus produce a material for briquettes containing less ash than the coal itself. In the same way where there was waste material containing coal dust they could separate the coal from the dirt and produce good coal for briquettes containing less ash than the primitive coal. He had recently burned some of these successfully. Some month ago he sent a short communication to the "Journal of Gas Lighting," which had been treating as a problem the use of common gas coke as a domestic fuel, in order to show that there was no problem. He always burned coke in his own house and would not have coal for the living rooms. He

did not have any special appliances for burning the coke, but merely used an ordinary well fire with the iron grid removed and the ash pit filled with common brickbats; if there were any secret in the burning of coke in a domestic fire it was to have no iron, iron being poison to a coke fire, and to have no draught. The violent draught needed in a small coke fire burning in an iron surround was not required if the coke was put in a heap on a brick ground with a firebrick back, in which case no air could get to the coke except that which came in at the front and went out at the top. A small coke fire with its small natural draught would keep alight an incredibly long time, producing a dull red heat which would throw a gentle heat into the room; if a larger fire were made it would induce a stronger draught and the stronger draught would in turn make the fire hotter. A coke fire became red hot and gave a proper heat into the room in less time than a coal fire, because there was no distillation process going on first. All that had to be done to such a fire to keep it in order was to put a poker underneath it two or three times a day just to lift it up so that the ash could filter through and fall to the bottom. All the coke dust and small was simply put carefully on the top of the fire when the fire was burning well and it remained there and burned away, so that there was no waste.

MR. CHARLES CARPENTER, D.Sc., said he had very much enjoyed listening to the paper and wished to join with the other speakers in congratulating the author upon its delivery. With regard to the advantages of gas lighting, to which the author had referred, a new school was arising to-day which seemed to think that gas lighting was a thing of the past. He thought it was the greatest possible mistake to tell people that and to advise them to have their houses lighted by electricity. It was true that during the war there were certain irregularities in the composition of gas which made its use, not only for lighting but also for heating purposes, not altogether free from inconvenience, but that was a state of affairs for which there was no justification at the present time. There was no reason why gas should not be used now for lighting with the same certainty of obtaining definite results, the same simplicity, and the same absence of care and attention, as obtained in the case of electric lighting. In order that that should be so it was important that attention should be paid to another matter to which the author had referred. The author had quite properly drawn upon his German experience for an example and had shown that it was most essential that if a definite quantity of a dye was taken it should under all circumstances give a definite result. If the normal 99 or even 100 per cent. product was distributed there might be occasions when the quality would fall slightly below and the result would be extremely detrimental to the

dyers' work, but by the system to which the author had referred of lowering, as it were, the product to a definite percentage it was possible—and the process was carried out on a large scale—to obtain absolutely definite results from the product which the German dye producer put on the market. That method was exactly the one which should be encouraged by the gas engineer in the matter of the composition of his gas, and it was one respect in which the chemist could be of enormous use to the gas engineer in his operations. He thought that in the past the gas engineer had thought far too much of volume. Thanks to the proposals of Sir George Beilby and the Fuel Research Board, that had now been altered and gas engineers now talked of therms instead of cubic feet. He would suggest that young engineers should train themselves up in that method of expression and should impress upon those who still practised the old method the importance of speaking in the language of exactness.

PROFESSOR H. E. ARMSTRONG, F.R.S., said that he could best express his feelings in the words of a great Victorian poet: "Come to my arms, my beamish boy," and chortle in his joy. He had waited years for that evening. Mr. Evans had termed himself a gas-chemist. He (the speaker) objected to any qualification of the term "chemist"; a man was or was not a chemist; but whatever he might be as chemist, Mr. Evans was an artist and a poet. He had given them a variety entertainment that could not conceivably have been set before gas-men ten years ago, when he, and perhaps one or two more, were the only chemists attached to gas companies. The use of the chemist, in fact, only dawned upon the industry after the outbreak of the late war; now, at last, he was regarded as indispensable to its success.

He could not let the opportunity pass of paying tribute to the extraordinary service Dr. Carpenter had rendered, by his efforts, to put the industry upon a scientific basis, to standardise gas and to supply honest goods; there was very great danger, however, that his example might not permeate through the mass. Though Mr. Evans had not attempted to paint the town red, it seemed he had tried to stain gas blue. Blue, perhaps, was a little symbolic of the gas works; they spoke of blue-water-gas, and he was inclined to think that they were in a "blue funk" as to their future, the state of the industry being now a serious one. Reference had been made to the subject of carbonic oxide. He thought a great debt of gratitude was owing to Dr. Bone for having raised the question. In a very short time Dr. Bone had done that which chemists had unsuccessfully long striven to do—he had taught the public that there were two oxides of carbon and he had taught people to know the names of both, to distinguish between them and to realise that one was com-

bustible and the other incombustible. A good deal had been said about gas being poisonous. It was, but mainly to such as put their heads into a gas stove for suicidal purposes. It had been his privilege to be invited by the author to visit the laboratory of the South Metropolitan Gas Works to witness the smoking experiments to which the author had referred and he had been surprised at the results, which were very startling. It was found, taking an ordinary cigar, that only about one-third excess air passed through it, so good an instrument as a stove was a cigar. He took it that few stoves had that efficiency; most of them passed a good deal more waste air. There was a ratio of carbon dioxide to carbon monoxide of only two to one, so perfect was the reduction. In one analysis that he carried out there was 6 per cent. of carbonic oxide, and the better cigars gave more. If one thought what the atmosphere of a first class railway carriage with half a dozen people smoking in it must be like, it would be realised that, if carbon monoxide were dangerous, the small amount met with under ordinary circumstances was not likely to be harmful. A distinguished physiologist told him a few weeks ago that he could always detect carbonic oxide in his blood. With regard to sulphuretted hydrogen, he did not think it was necessary to pay such special attention to that, but the sulphur that was left in other forms was a very serious matter, and did far more harm than carbonic oxide. His own house was on the South Metropolitan supply, and, small as was the amount of sulphur in that company's gas, objects which had been exposed to the gas showed most serious deterioration under the influence of sulphur. Dr Carpenter had been endeavouring to get rid of the sulphur and had done a great deal in that direction. He understood the work was being carried on at the present time and that improvements were likely to take place, and he looked to Dr. Carpenter to remove the last disability from gas. If gas could be obtained free from sulphur there would be very little to be said against it. At a meeting of the South Metropolitan Gas Company held that day he said in the course of his speech that Dr. Bone had at the back of his head something far more important than the poisonous effects of carbonic oxide, i.e., the thermal value of the gas. There was an attempt being made throughout the country at the present time to persuade people into the view that a low thermal value was preferable, but he was sure that was not the case. What was really wanted was a gas of as high a thermal value as possible if gas appliances were going to be improved and made more suited for use in the future. There had been a good deal of discussion recently on the subject of the feeding of schoolboys, and one point that should be realised in that connection was that food nowadays was not nearly so good as it used to be because of the way in which it

was cooked. The open range had been given up and people had taken to the gas stove, with the result that there had been a very serious deterioration in the value of food. That was only gradually being appreciated. If a gas cooker could be made on the lines of the open range of the past, an immense gain would result. The wonderful burner produced by Dr. Bone some years ago was of that order; there was a blazing surface which was superior to that of the old fashioned stove and nothing could be more perfect for use in grilling and roasting, but unfortunately the flame lit back. The hope of obtaining improved gas burners lay in the direction of getting improved gas. With regard to smokeless fuel, the author had been pleading in favour of a fuel made by using up the coke that the gas industry produced. Everybody, however, was not going to burn coke in the clever way Prof. Boys burned it. After all, the amount of coal used by the gas companies was only about 10 per cent. of the total amount used, so that it did not very much matter what they did with their coal. The rest of our coal was not going to be treated in the way that the gas companies treated their coal, and it would therefore have to be distilled in a way that would enable as much oil as possible to be obtained from it. The low temperature oils obtained could be used as fuel oils straight away, and other uses might be discovered for them. When coal was thus distilled, after it had been treated in the way Prof. Boys had indicated, a fuel was obtained which would burn with extraordinary ease and with a minimum of ash. If the small coal to which Prof. Boys had referred was stored for any length of time it deteriorated and became oxidised and very little oil could be obtained from it, but if it was carbonised at a low temperature a material was obtained which would keep apparently for any length of time. It had not been under observation for very long, but during the ten years that it had been kept it had not changed in the very slightest degree. By low temperature carbonisation the coal would be stabilised and small coal could be converted into a solid material comparable with the largest and best coal and at the same time a gas would be produced of the quality which Dr. Carpenter was bent on giving to the public. His own view was that, whatever the gas industry might choose to do now, in the long run they would be forced to become makers of low temperature smokeless fuel and obtain gas in so doing, the gas being a by-product, and they would supply the public with fuel. The one curious result of that would probably be that the dye-stuff industry would disappear, unless the materials required could be made in other ways than from coal tar. There were other sources of some of them in sight, as for instance, the petroleum oils. In conclusion, he wished to say that the paper had been of extraordinary interest and value, charmingly

delivered, and one displaying an unusual amount of imagination.

MR. F. GLOVER said those present were indebted to the author for a very interesting paper which drew attention to some very important facts connected with our national life. Very novel methods for avoiding the smoke nuisance were sometimes put forward, but it was often forgotten that the gas industry was already contributing in an enormous degree to the reduction of town smoke. The gas industry produced in the solid form something like 8,000,000 tons of coke and for the most part that coke was used in this country and must be contributing substantially to the reduction of smoke, because if those 8,000,000 tons of coke were not there 8,000,000 tons of coal would have to be used instead, and those 8,000,000 tons of coal would produce a very considerable quantity of smoke, besides a very considerable quantity of sulphur, which would be turned into the atmosphere and converted into sulphuric acid. The gas industry were doing a very important work in extracting the sulphur and making it into sulphuric acid in sulphuric acid chambers and using it in the industry. It was also forgotten sometimes that of the 20,000,000 tons of coal carbonised in gas works something like 10,000,000 tons was required for fuel purposes, and in that way the gas industry made another contribution to the smokelessness of towns. Coke was a very valuable smokeless fuel but the precision of the chemist was needed to remind those who sold coke that they ought to sell coke and not coke and water. More care should be taken in the choice of coal for gas making if there was to be a good finished product in the form of coke. The ash originally contained in the coal was concentrated in the coke, and therefore weight for weight more ash was obtained from coke than from coal, whichever way the coal was carbonised, and to remove the excess impurities from gas coal was a very important function of the colliery owner. That had not been sufficiently realised in some coalfields, and the coalfields from which the London gas companies drew their supplies were the worst sinners in that respect. The Yorkshire colliery owners had put down modern coal cleaning plants and had reduced the ash in the coal very considerably, to the great benefit of the coke. It was no use making good coke fairly free from ash if it was treated as a residual. He did not like the word "residual"—it ought to be "by-product"—but the coke was too often treated as a residual; it was taken from the retort house and dumped in a heap where the rain could fall upon it. It absorbed a great quantity of water and was sold to the customer with varying quantities of water in it; the buyer had to drive that water off by the heat of his fire, a great many heat units being thus lost in the form of latent heat in the steam. The chemist should impress upon the gas engineer

that it would be very much better if he took more care in producing smokeless fuel, to store it under cover and to fit it for the consumer, so that the greatest possible number of thermal units might be obtained from it when it was burned. The coke produced from the latest form of retorts, the vertical retorts, was made absolutely dry and ignited much more readily and burned much more cheerfully than other coke, that being the case particularly when continuous vertical retorts were used. The coke produced in the future would therefore be much more satisfactory, and the difference had already been noticed in those towns where that new method of carbonising coal had been adopted. He was very glad to hear from the author that the South Metropolitan Gas Company had overcome the "naphthalene bogey" and it was very gratifying to find that the oil washing process which had been advocated for so many years was very effective when used in a proper and thorough manner, as was done under Mr. Evans' control.

MR. T. HARDIE (President of the Institution of Gas Engineers) said it was very satisfactory to hear from the author that he had been able to reduce the naphthalene stoppages to such an enormous extent. With regard to carbon monoxide, it was well known to those who produced gas that for the last eight years there had been as much carbon monoxide in it as there was at the present time. Turning to the subject of low temperature carbonisation, he did not think gas engineers would ever agree to become primarily oil producers. They were out to make gas and it was their intention to make gas, and, although in producing gas they might produce other things as well, they would continue to be first and foremost gas engineers.

MR. DAVID BROWNLIE said with regard to the question of low temperature carbonisation *versus* high temperature carbonisation, the author was in favour of the latter, but personally he thought that was wrong. If the history of the gas industry from the time when it started, about the year 1795, was studied, it would be found that the temperature had been gradually increased in order to try to obtain more gas, making it weaker and weaker. He could remember the time when gas would actually light and give a candle power, but to-day nobody would accuse gas of giving any candle power! He took it the ideal of the gas industry was to have total gasification, to make one ton of coal give 50,000 ft. of gas with 30 per cent. of carbon monoxide. In his opinion the right method to adopt was not to try to take the 30 per cent. of volatile matter in the coal and convert it into gas, but the right method was the low temperature method of converting that 30 per cent. of volatile matter into no gas at all but all into oils and fuels.

MR. E. V. EVANS, in replying to the discussion said that with reference to Dr. Haldane's remarks he did not suggest that the miner had a shorter life than other people. His point was rather that the lungs did become in the condition he had described, and he would like to ask those present, bearing in mind what Dr. Haldane had said on the subject, which they would rather have — clean lungs or "black spit," as Dr. Haldane called it. Prof. Boys' remarks on the flotation process were of considerable interest; the sample of fuel which had been burned on the premises had been treated by that flotation process and it had certainly shown itself to be an admirable fuel. As to Prof. Armstrong, he was in Mr. Evans's opinion, the greatest living chemist. They had often talked together about low-temperature carbonization. This process was certainly an interesting one; and the fuel made was a fine material for the domestic hearth. These conversations with Prof. Armstrong and the results of his examination of low-temperature fuel, had caused him not only to advise the gas industry to beware of competition in the future from this material, but had stimulated him to work out the manufacture, as a gasworks by-product, of a domestic smokeless fuel. He believed he had been misunderstood by Mr. Glover, because he was assuming that in the future the domestic raw coal at present delivered to a town should first be dealt with at the gas undertaking, which would then deal with a larger quantity of coal, obtaining cheaply a greater output of gas. He suggested that the gas industry could deal not only with the industries it was dealing with now, but also with the domestic fuel industry; for he felt certain that a time would come when a low-temperature carbonizing industry would come about if the gas industry did not take the steps to secure it.

On the motion of THE CHAIRMAN, a hearty vote of thanks was accorded to Mr. Evans for his interesting paper and demonstrations, and the meeting then terminated.

GENERAL NOTES.

NON-FERROUS METALS RESEARCH.—The second annual meeting of the British Non-Ferrous Metals Research Association was held at Birmingham, on March 2nd. Mr. T. Bolton, who presided, comprehensively surveyed the activities and progress of the Association which has now over 100 member firms. A number of important investigations are being conducted by the Association in various laboratories. He emphasised the fact that division of labour is as important among brain workers as among hand workers and co-operative research is the best and most economical method. He referred

particularly to the proposal of the Association to establish University Fellowships for post-graduate research. One of the speakers was Sir Frank Heath, Secretary to the Department of Scientific and Industrial Research, who gave several illustrations to show the value of co-operation between user and producer. He thought the provision of an intelligence service was one of the most valuable things an Association could do. He was also, he said, particularly interested in the projected establishment of research studentships and he offered the assistance of his Department in working out a scheme. The growing appreciation of the value of research was, he added, indicated by the absence of any reference to his Department in the proposals made by the Geddes Committee.

THE THEORY AND PRACTICE OF ACID MIXING.—A special series of reports is being published for the Department of Scientific and Industrial Research in order to make available, for the benefit of the industries concerned, results of scientific and industrial value contained in the technical records of the Department of Explosives Supply of the Ministry of Munitions. The work recorded was done at or in connection with some of the National Factories during the War. The preparation of the necessary abstracts of information was begun by the Ministry of Munitions at the close of the War, and arrangements were afterwards made by the Department of Scientific and Industrial Research to complete them. Copies of these reports may be obtained from H.M. Stationery Office. The fourth and latest report, "The Theory and Practice of Acid Mixing," is dealt with under the following sections:—Section 1 Acid Cycles, Acid Balances and Control of Plant Output. Section 2. The Position of the Acid Mixing Plant in the Acids Cycle and the Procedure adopted in Mixing. Section 3 Plant and Process for Acid Mixing.

INDIAN PEARLS AND "CULTURED" PEARLS.—In view of statements to the effect that Japanese "Cultured" Pearls are indistinguishable from, and equal in value to, Indian pearls, and in order to re-assure possessors of pearls, a number of firms on their own behalf announce that the value of Indian pearls is not affected by the introduction of 'cultured' pearls, the reasons given being:—(1) "Cultured" pearls are beads covered with pearl nacre of varying degrees of thickness. (2) They can only attain a comparatively small size, and on account of their quality do not compete with Indian pearls, from which they can be distinguished. (3) They cannot be compared with pearls, any more than rolled gold with solid gold, or electro plate with silver. The French *Chambre Syndicale* have forbidden their entry or sale in Paris as pearls.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, MARCH 13. People's League of Health, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Sir Frederick Mott, "Mind and Body."

University of London, King's College, Strand, W.C., 5 p.m. Rev Prof S. W. Green, "Idolatry."

Electrical Engineers, Institution of (North Eastern Centre), Armstrong College, Newcastle, 7.15 p.m. (Dundee Sub-Centre), University College, Dundee, 7.30 p.m. (1) Mr. J. Anderson, "Electric Motor Starters." (2) Mr. L. H. A. Carr, "Induction Type Synchronous Motors."

Transport, Institute of, at the Institution of Civil Engineers, Great George Street, S.W. 5.30 p.m. Mr. T. R. Johnson, "Railway Problems in China and Australia."

Geographical Society, Kensington Gore, S.W. 5 p.m.

TUESDAY, MARCH 14. Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Annual General Meeting.

Rubber Industry, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.30 p.m.

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Lieut.-Col. L. S. Amery, "Migration within the Empire."

British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 7.30 p.m. Mr. P. A. Wells, "Painted Furniture, Old and New."

Textile Institute, 16, St. Mary's Parsonage, Manchester. Mr. W. Harrison, "The Human Element in Industry."

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Mr. J. P. Mills, "The Lhota Nagas."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Annual General Meeting.

Metals, Institute of (Local Section), at the Chamber of Commerce, New Street, Birmingham, 7.30 p.m. Mr. D. H. Ingall, "The Mechanical Properties of Pure Rolled Zinc" (Scottish Local Section), 39, Elmbank Crescent, Glasgow, 7.30 p.m. (1) Annual General Meeting. (2) Dr. R. S. Hutton, "Motion Study and its Application to Training (with particular reference to Metal Polishing)."

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, Piccadilly, W., 4.30 p.m. Prof. A. J. Toynbee, "The Break-Down of the Eastern Frontier of the Roman Empire in the Seventh Century, A.D. Its Antecedents and Parallels."

Royal Institution, Albemarle Street, W., 3 p.m. Sir Arthur Keith, "The Anthropology of the British Empire" (Lecture IV.)

University of London, at the Royal School of Mines, Imperial College, South Kensington, 5.30 p.m. Colonel N. T. Belauw, "The Crystallisation of Metals" (Lecture IV.)

Anglo-French Society, Scala House, Tottenham Street, W., 6.15 p.m. M. M. Thiers, "La Vaudeville."

Electrical Engineers, Institution of (North Midland Centre), Hotel Metropole, King Street, Leeds, 7 p.m. (Scottish Centre), North British Station Hotel, Edinburgh, 7 p.m. Mr. E. S. Bmg., "Telephone Line Work in the United States."

Asiatic Society, 74, Grosvenor Street, W., 4.30 p.m. Mr. L. Shuttleworth, "Some Peoples and Religions of the Punjab Himalayas."

WEDNESDAY, MARCH 15. Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Mr. W. H. Dickinson, "The Organisation and Conduct of Tuberculosis Dispensary Work." Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. W. Piercey, "Psychology in Industry."

Microscopical Society, 20, Hanover Square, W., 8 p.m. Mr. J. E. Barnard, "The Future of the Microscope in Medical Research."

Meteorological Society, 49, Cromwell Road, S.W., 7.30 p.m.

Electrical Engineers, Institution of (South Midland Centre), The University, Birmingham, 7 p.m. Mr. J. Anderson, "Electric Motor Starters." (Sheffield Sub-Centre), Royal Victoria Hotel, Sheffield, 7.30 p.m. Mr. F. Langley, "Notes on the Practical Operation of E.H.T. Protective Gear."

THURSDAY, MARCH 16. Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Dr. V. E. Pullin, "Radiological Inspection Work."

University of London, King's College, Strand, W.C., 5.15 p.m. Prof. Nils Bohr, "The Quantum Theory of Radiation and the Constitution of the Atom" (Lecture II.) At the London School of Medicine for Women, Hunter Street, W.C., 5 p.m. Dr. H. H. Dale, "Some Recent Developments in Pharmacology" (Lecture IV.)

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Annual General Meeting.

Royal Society, Burlington House, Piccadilly, W., 4 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Dr. L. D. Barnett, "The Hindu Culture of India" (Lecture III.)

Chromatics, International College of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. A. D. Stocker, "Life and Colour, from the point of view of Therapeutics."

Anglo-French Society, Scala House, Tottenham Street, W., 6.15 p.m. M. Emile Cammaerts, "La Poésie Moderne de la Langue Française" (Lecture II.)

Royal Institution, Albemarle Street, W., 3 p.m. Dr. P. Chalmers Mitchell, "The Cinema as a Zoological Method" (Lecture I.)

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. Mr. J. G. Hill, "Phantom Telephone Circuits and Combined Telegraph and Telephone Circuits worked by Audio Frequencies."

Transport, Institute of, Preston Mr. T. W. Royle, "The Importance of Detail and its Place in an Efficient Railway Organisation."

Dyers and Colourists, Society of (West Riding Section), Leeds Messrs. L. G. Radcliffe and B. G. Shatwell, "A Synthesis of Glycerine and a Novel Chemical Reaction."

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. (1) Mr. H. B. Baker, "Change of Properties of Substances on Drying." (2) Messrs. H. Burton and J. Kenner, "The Influence of Nitro-Groups on the Reactivity of Substituents in the Benzene Nucleus." (Part VI) "The Elimination of Halogen during the Reduction of Halogenated Nitro-compounds."

FRIDAY, MARCH 17. Transport, Institute of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Mr. F. Pick, "The Operation of an Omnibus Company, with reference to Capacity and Cost under given Conditions." University of London, King's College, Strand, W.C., 5 p.m. Prof. R. Robinson, "Orientation and Coupling in Organic Chemistry from the Standpoint of the Theories of Partial Valency and of Latent Polarity of Atoms" (Lecture III.)

Royal Institution, Albemarle Street, W., 9 p.m. Principal A. P. Laurie, "The Pigments and Mediums of the Old Masters."

Metals, Institute of (Local Section), The University, Sheffield, 7.30 p.m. Mr. W. R. Barclay, "Some Nickel Alloys."

Japan Society, 20, Hanover Square, W., 5 p.m. Rev. W. Weston, "Some Aspects of Rural Japan."

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m.

Dyers and Colourists, Society of (Manchester Section). (1) Prof. A. J. Turner, "The Influence of Humidity on Textiles." (2) Mr. W. H. Norris, "Detection and Prevention of Loss of Material in Dye and Chemical Works."

Chemical Industry, Society of (Local Section), The University, Liverpool, 6 p.m. Dr. W. E. Gibbs, "The Industrial Treatment of Fumes and Dusty Gases."

Electrical Engineers, Institution of (Students' Section), Savoy Place, Victoria Embankment, W.C., 7 p.m. Mr. C. C. H. Wade, "The Electron Theory."

SATURDAY, MARCH 18. Royal Institution, Albemarle Street, W., 3 p.m. Sir Ernest Rutherford, "Radioactivity" (Lecture III.)

*Announcements intended for insertion in this list must be received at the SOCIETY'S Office, not later than the Monday morning of the week preceding the Meeting.

*For Meetings of the ROYAL SOCIETY OF ARTS, see page 291

Journal of the Royal Society of Arts.

No. 3,617.

VOL. LXX.

FRIDAY, MARCH 17, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MARCH 20th, at 8 p.m. (Cantor Lecture.) GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, "The Constituents of Essential Oils." (Lecture 1.)

WEDNESDAY, MARCH 22nd, at 8 p.m. (Ordinary Meeting.) A. P. LAURIE, M.A., D.Sc., F.R.S.E., H.R.S.A., Professor of Chemistry to the Royal Academy of Arts, "The late Mr. Holman Hunt's Experiments on the Permanency of Artists' Oil Colours." Sir ASTON WEBB, K.C.V.O., C.B., P.R.A., in the Chair.

FRIDAY, MARCH 24th, at 4.30 p.m. (Indian Section.) Professor HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India." Sir THOMAS HENRY HOLLAND, K.C.S.I., K.C.I.E., D.Sc., F.R.S., in the Chair.

FIFTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 8th, 1922; MR. JOHN MURRAY, M.P., in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Anderson, Alexander James, C.S.I., Haslemere, Surrey, and Rangoon, Burma.

East, Alan Neville, A.M.I.E.E., A.M.I.Mech.E., London.

Lloyd, Albert Lawrance, London.

MacIsaac, Donald Francis, B.A.Sc., Sydney, Nova Scotia.

Phillips, Frederick, B.Litt., Deganwy, N. Wales.

Sanders, Gerald Worsdall, Apperley Bridge, Bradford.

The following candidates were balloted for and duly elected Fellows of the Society:—

Basu, M. N., Calcutta, India.

Hayes, Sidney George, Ilford, Essex.

Orton, Charles James Swaffield, Broadstairs.

Rajhavan, S. Srinivasa, B.A., B.L., Madras, India.

A paper on "The Proper Functions of Trade Unions" was read by Mr. W. A. APPLETON, C.B.E., Secretary to the General Federation of Trade Unions.

The paper and discussion will be published in a subsequent number of the *Journal*.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1921 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 25th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce."

The list of those who have received the medal since its institution in 1864 was printed in the last number of the *Journal*.

PROCEEDINGS OF THE SOCIETY

TWELFTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 15TH, 1922.

SIR HENRY NEWBOLT, C.H., D.Litt., LL.D., Chairman of the Departmental Committee on the Teaching of English, in the Chair.

The paper read was:—

THE NEED OF SPEECH TRAINING AND THE NECESSITY FOR A NATIONAL CONSERVATOIRE.

By CLOUDESLEY BRERETON.

The other day I heard of a theatrical manager who engaged for the leading lady in a new play a totally untried tyro, simply because she "looked" the part he was wanting to fill. All she had got to do, so he told her, was to be "natural."

Now many people may, more or less, look the part till they open their mouths. They look indeed like an angel, but talk like poor Poll, to quote the well-known epigram on Goldsmith. Maître Corbeau doubtless appeared a kind of super-black-bird, not only to himself, but to many others, till the fox induced him to give a specimen of his singing qualities. Moreover, different circumstances demand different types of naturalness. What may pass for good form at the Ritz would be out of place in Westminster Abbey. The actor is a chameleon, who takes his colour and his cue from his surroundings. His role is not so much to be natural as to appear so. That is the real "paradoxe du comédien." Nor is it merely a question of looks, but of speech. A person who talks naturally in a drawing room will very probably be inaudible on a big stage, especially in this country, where it is unfortunately *natural* for the great majority of persons to be inaudible at a comparatively short range. Of course, there are a few long range speakers like the late Mr. Gladstone, who used to address Queen Victoria as if she were a public meeting, but it seemed the reverse of natural to Her Majesty. Even if a person has a natural singing voice, it is now universally agreed that she cannot sing in grand opera without a long and elaborate training. Yet it is still widely denied that training, even for the actor, is necessary in the sister art of Diction. That, however, was not the belief amongst the ancient Greeks and Romans, nor is it either the belief among their modern representatives—the French.

This theory of being "natural" is part of the ultra-individualism of the day. Germany was full of this *temperamentvoll* doctrine before the war. "Be yourself" seems so much easier than the older doctrine "know yourself." Hence its wide popularity to-day, though as a theory and a catchword it has existed with very varying meanings for centuries. The Stoics made it the master-key of their doctrine. Live naturally, they said. Rousseau was all for a return to Nature. The comment in each case is "Yes," but what kind of nature? Stated in this skeleton form, the doctrine is so general that it means nothing in particular, or else implies everything. It is no doubt true as far as it goes, but it is about as helpful as saying that the whole of medicine is summed up in the phrase

"keep well." That brings us "no forader," and renders hospital clinics and the *materia medica* every whit as indispensable.

The cult of uncultured nature in the XXth century is nearly as great a myth as the cult of the uncultured savage in the XVIIth. It derives no little force from the general revolt against authority, which, in the realm of art, takes the form of a revolt against technique itself, and as such is mainly due to a misapprehension of technique itself and its functions. What, then, is technique?

It is nothing more or less than the *generalised* experience of the art or craft concerned, be it painting or sculpture, diction or dancing. It is not a substitute for, but ancillary to creative work. Those who are misled into believing the former, acquire the whole world of technique and lose their own soul. That is the tragedy of many a *prix de Rome*. But its presence in any really creative work only adds greater richness and ripeness to it. Education, whether on Montessori or other lines, has for one of its chief aims and objects the imparting of technique, or a knowledge of the tools of learning and expertness in using them. Technique from this aspect is the self-imposed yoke whose service is perfect freedom, for without it freedom is mere licence. Or, in other words, the greatest artist consciously submits to technique in order to triumph over it, being ever ready to break any one of its rules in order to achieve greatness, but not to break them all at once, for that were mere anarchism—ready again, when he had broken them, to explain why he did so. Every supremely great artist is a potential Antigone whose breach of the highest conventions is justified by the results, and all the more readily explainable by the artist himself, the more profoundly he is acquainted with the existing canon of conventions, which like a Judge of the Supreme Court he is perpetually *interpreting*, and re-stating. The greatest artists, the Leonardos and the Phidiases are those who have pondered the deepest on their art and turned the searchlight of their consciousness on the productions of their subliminal selves.

Of course, without inspiration there can be no true art. But *vis consili expers mole ruit sua*, and inspiration even in its happiest and apparently most spontaneous moments

depends on calling into play that previous experience of a life-time external or internal of which Whistler spoke. If the painter or poet is to utter adequately the thoughts that arise in him, among the forces he mobilises for self-expression for creating the outward and visible symbols of his passion, are just those technical experiences he has been amassing consciously or unconsciously during the preceding part of his life.

This is the true element in the saying that genius is infinite capacity for taking pains. Genius always does take infinite pains, though the result may only be ultimately revealed by the shortening of the artist's life. Qualitatively a genius may live 10 years in 10 days, and die at 30. But whether those pains be the work of the brooding spirit within or the birth-pangs of self-expression, in either case or both, they may be lightened and alleviated by studying the generalised experience of the particular art or craft concerned, always bearing in mind that one cannot get hold of too much of this experience if one looks at it not as a set of immutable laws, but as so many starting points for further discovery, truths up to date and nothing more, though some of them may remain unaltered for centuries, like the law of gravity, till an Einstein comes along.

If technique then is essential in all the arts, what is its role in speech training? Surely here as elsewhere it has for its function the handing over of the acquired lore of the elocutionary craft, which, while it differs in its applications according as it deals with pulpit eloquence, public-speaking, platform recitation, dramatic work or the mere speech of the average school-boy, can none the less roughly be sub-summed under the four headings of gesture, pronunciation, intonation (including pitch and stress) and rhythm. These form, so to say, the four chief divisions of the grammar of the subject—its quadrivium, in fact.

I. Gesture is really the rudimentary and primitive language of mankind. Whether the acquisition of language be more difficult for English people or not may be a moot point, but certainly the language of gesture is more difficult for them to acquire than for other folk. Not infrequently the gestures of an English speaker are not only inexpressive and incongruous, but even distracting. Quite recently I was listening to a speech by a well-known English poet.

What he had to say was highly interesting, but at regular intervals in his speech his right hand sought the back of his head and gently patted it in order apparently to ascertain whether he had lost his back hair or not. Such a proceeding might possibly be justifiable in the case of a veteran like myself, but it was a highly unnecessary precaution in one so young. One ended by being, as it were, fascinated by the recurring action in the same way as one is fascinated by a regularly recurring flash-sign at night—one cannot choose but look—be it Veno's Lightning Cough Cure or Edwards' Desiccated Soup. This capillary attraction (to come back to our poet) grew so overwhelming that the speech became of secondary interest, and one realised once more the profound dictum of Bergson on the comic element that comes to the front when life masquerades as a mechanism.

Possibly the reason for this lack of spontaneity in our gestures is partly physical. Our raw and damp climate which discourages us from opening our mouths so wide as our continental neighbours, lays its rheumatic grip on our muscular activities. But it is also physical. This conservation of physical energy is due to our concentration of will power, our outstanding English characteristic, with its corollary of perpetual self-control of the emotions. We do not let ourselves go easily. We are either rigid or violent. (Gesture to a Frenchman, and still more to an Italian, is a second language—a commentary, accompaniment and explanation, all rolled into one, of the spoken word. With an Italian, pantomime and Dumb Crambo are so perfect, that even if you do not know his language you can get hold of the general drift of his meaning. I remember once an Italian singer in Berlin with the two Lehmanns in Don Juan. The two prima donnas, fat, fair and forty, who looked like two deserted landladies, concentrated their artistic efforts on the singing. Not so Andresda; he frisked round them, putting such brio into his attentions that he almost persuaded one they must be beautiful.

But gesture, except of the clown order, in which the Englishman is supreme, occupies a more subordinate position on the English stage, though it is not infrequently overdone. Years ago I asked Coquelin aîné, at the time of one of his visits to London, what he thought of English acting. As

everyone had been so kind to him, he begged me, whatever he said, to keep his opinion private for the time, which I promised to do. He then said that he made the same criticism of Irving and Tree that Garrick made over 100 years ago of the French actors of his day, that they overdid their parts. But over-acting, as a friend has pointed out to me, is like the child thumping the piano, only force ill-applied in the desire to obtain an effect, and as such is indicative of imperfect control of one's own mechanism.

Still, if gesture is only subsidiary compared to its importance in France and Italy, its study is none the less essential not only for actors, but for public speakers, even though it lead to no more than teaching them what *not* to do with their unruly members, be they feet, hands, or head.

II. I pass to Pronunciation—for a long time supposed by the phoneticians to be the end-all or be-all of correct speech. Happily, of recent years, they have gradually realised the supreme importance of intonation, especially from the point of view of musical pitch, which varies for each language. As I take it, pronunciation deals with *correct sound*, intonation with *correct meaning*. The former takes words or syllables as its unit, and the latter phrases or sentences. These two things at bottom represent two totally different things, as anyone who has had to teach a child to read knows. The child may read a passage with absolute correctness as far as sounds go, yet it is so lifeless and mechanical that the hearer is obliged to say it over to himself in order to interpret it, just as we are obliged to say over to ourselves the sounds of some phrase we have heard in a foreign language, if we have failed to understand it when it was uttered. As to the teaching of pronunciation, with which I include enunciation or the art of making clear sounds, that is the business of the voice-producer and phonetician, who should always work together, though such is by no means always the case. Such training is especially necessary for the average English speaker with his blurred vowels and slurred consonants.

III. I pass to Intonation, which deals, as we have seen, with musical pitch and under which, for the sake of convenience, I include pause and stress. The usual forms of affirmation, order or question in the different languages can all be set down

in musical notation as well as the ordinary ways of expressing such common emotions as anger, surprise or fear. But intonation is not only this: it seems to me at best something far more subtle, so subtle as to defy any concrete notation. Thus, in the two phrases, "he took a pail and went into the garden," and "he saw a pale face in the garden," I cannot help feeling there is, apart from the stress on the two words, some very subtle difference made by a reader who visualises as he reads, because I cannot believe, if his visualisation of the two things differs that his outward exteriorisation of the two is not also a matter of tone as well as stress. Intonation is above all interpretation.

But the most perfect intonation without the appropriate soul behind it is as sounding brass or a tinkling cymbal. I think that many will agree that Coquelin aîné was in some ways the greatest and most finished actor in technique of his time. I remember seeing him one day in that scene in *Thermidor*, where they are seeking for the papers of some hapless prisoner to substitute them for those of the hero already condemned by the Commune. At last they come across those of an individual with no family ties or dependants. On the point of making the substitution Coquelin refuses with the simple words "Après tout c'est un être humain," words which always thrilled the audience. Years after when speaking of Coquelin with Réjane I quoted the words to her and said I wondered why Coquelin never attempted tragedy. According to Réjane he had. In the first act he was mediocre, in the second worse, and in the third the audience actually laughed. He never tried a tragic part again. I mention this as it seems to me an admirable instance of the *limits* of technique.

Stress and pause are, of course, important, neglect of them results in such blunders as the child's rendering of the hymn: "Can a mother's tender care cease towards the child she-bear," as she phrased it, and the puzzling remark of a small boy of six to me in Berlin, a brother of Hubermann, the violinist, who, when I asked where he lived when staying in London, said *Sixty-Tomarkis Road* (62, Marquis Road). Stress again is no simple matter of stress and non-stress. There are probably infinite degrees of stress. A French phonetician has, I think, asserted there are in *indivisibilité* seven different degrees of stress,

but please don't ask me which they are. The whole matter is, indeed, highly complicated, but I hope I have said enough about it to show what fundamental brain work the study of intonation involves.

IV. And, lastly, I come to the question of rhythm, which in some ways seems to me the most fundamental of all, since it is the key to the *mood* of the author under study. Of course, it is not to be confounded with rhyme, on which a few words will be said later on. Still less is it to be confounded with metre.

The supreme quality of rhythm is that, though in verse, as a rule it falls into certain definite generic types, of which metre provides the scheme or skeleton outlines, within those limits it is unique, varying *ad infinitum* for him that hath ears to hear. Indeed, it is no paradox, but the sober truth to say that if one writes a stanza on a certain rhythm one day, it is impossible to write a stanza identical in rhythm to it the next day. It has, of course, a family likeness. It may be better, it may be worse, but it is not identical. One cannot bathe twice in the same river. Rhythm possessed what Bergson calls the irreversibility of life, it is indeed life itself. There are many bits of verse which are metrically correct, but they are not predominantly rhythmical, because they are devoid of life, although mechanically correct. They differ from real poetry as a piece of music played in strict dance time differs from the same piece when played with the endless *ralentandos* and *accelerandos* with which its composer has scored it. Of course, in prose the rhythm is freer, but in all good prose it is there, and correct phrasing in the recitation of prose is equally necessary for intelligibility. So many people seem to pause in recitation because they have no breath to go on, or they pause too long, whereby the rhythm is lost. Yet correct phrasing is of supreme importance, because the nearer we get to the author's rhythm, the more faithfully we interpret it, and the more faithful our interpretation, the greater our success in conjuring up in our own souls and in those of the audience the precise waves of emotion that thrilled him when he composed the poem or speech. We thus project ourselves and our audience into the very mind of the writer.

Just before the war there was a well known German phonetician whose name I have forgotten, who went so far as to

declare that if you wished to enter into the very soul of a composer you must not only play his works on the same type of instrument as he composed them on, but that you must copy all his little idiosyncracies as far as they are known, in the way of sitting, method of breathing, etc., in a word, you must attempt to put yourself into his skin. This is probably a counsel of perfection and raises the whole problem in the most acute form of what is correct interpretation, and the part to be accorded to the author, his interpreter, and the nationality of the latter's audience. But rhythm, fortunately, is like the language of music, world-wide in its appeal. Words may lose their meaning in translation, emotions be expressed in different pitch in different languages, but rhythm is a universal idiom.

Perhaps I may add here the promised footnote on rhyme. The principal question from the standpoint of diction is, should it be indicated or not? Rhyme is clearly connected with *pattern*; not to indicate the rhyme at all is to ignore the pattern. Generally, the indication will take the form of stress, slightly greater emphasis being laid on the rhyme, or it will take the form of a slight pause, or of a slight rise in pitch. The mood of the writer will dictate what is appropriate, and appropriate it is sure to be, unless the rhyme has been lugged in by the ears when its inappropriateness will at once be apparent. For reading aloud is the supreme test in this respect. Mr. Montague Summers lately stated that in a rhymed play recently performed by the Phoenix Society the indication of the rhyme by the actor, so far from being a hindrance, had added greatly to the effectiveness of the play.

So far I have mainly spoken of the need of training in diction from the point of view of the stage, because the theatre provides, as it were, a megaphone instance of the need for such training, inasmuch as any defect or shortcoming in the way of incorrect or imperfect speech being magnified a hundred times, so to say, on the stage, is rendered thus far more glaring. But the need for speech training is, as I have intimated, hardly less essential for members of other callings and professions, such as politicians, barristers, clergymen and even for more humble persons, such as lecturers and teachers like myself. Nay, we can go still further and say that it

concerns the entire population, and that our general methods of speech are so defective that, as the Departmental Committee on the Teaching of English has so vividly shown, the whole matter needs to be dealt with in the schools themselves, and that for many reasons, of which I will only take one, which is not utilitarian, and yet seems to me the most important of all.

It is that we have got to recover that joy in the spoken word, which is only second to the joy in song, that the majority of us possess at least in a rudimentary way. We have got to recover that joy in the spoken word which the most cursory reading of the Elizabethan dramatists, from Marlow to Beaumont and Fletcher, shows we once possessed, and which is so prominent a characteristic of the French. This is, no doubt, largely due to their being essentially a social nation, since the two main desiderata for intelligent and pleasant social intercourse are good manners and clear speech. But this does not mean we want to turn the English people into a nation of bores and spouters. I am not, indeed, aware from my intercourse with the French people that they turn out more bores or drivellers than other nations. On the contrary, I would venture to state that their conversation is, on the whole, far more sprightly and intellectual, no matter what class you take, than that of the corresponding grade in English society, in fact, the lower you go the greater the contrast. Broadly speaking, the average Frenchman appears to me instinctively to understand that correct speech and a clear way of putting one's thoughts is a duty not only to one's self, but also to the person one is addressing, such consideration being really one of the essentials of true politeness, which consists in sparing one's neighbours unnecessary trouble. Certainly, such clearness and such consideration tend to foster the particular atmosphere favourable to conversation, which even in these days of cinemas and cup ties, is still our greatest national recreation.

But where in the schools are we to begin? The answer is plain: with the children as soon as they enter, and the sooner the better. For all young children are born artists, and all love words and the sound and music of words, though this love may be crippled and finally crushed by the degenerate speech they hear around them. If we could only keep alive and foster

this love of the child for the living word, we should end by raising the level of the stage, just as one of the best ways of raising the quality of the artistic products of a country is to raise the level of taste among those that purchase them. Shoddy goods and pinchbeck gewgaws can only be sold to people who are content to purchase them.

I fear the idea of trying to make every child a speech lover will seem very strange and even absurd to some, and yet I hope to show conclusively it is not strange, much less absurd. We have for some time decided, rightly, I think, that even in our infant and elementary schools every child should be taught the elements of drawing and music, even though the vast majority will never become painters or public singers. Is it not then a little strange that we should still largely neglect the art of speech, which is used every hour of the day and all day, whereas the art of drawing and music enter only incidentally, if at all, into our daily life and conversation? If we try to cultivate the aesthetic sense in our children as far as drawing and music are concerned, why should we not *a fortiori* desire to do so in what is an universal art, especially as we have a language which with its numerous vowel sounds is more rich and varied than any continental language I know of? Does not our present spelling indicate from the mere fact that it no longer represents the sounds of many words how varied once was the music of our speech? Should we not, like the Society for Pure English, make a great effort to save some of that music which still remains in the speech of cultured people instead of allowing perhaps the most puissant language in the world to degenerate into a muddy, monotonous stream of slurred consonants and blurred vowels?

Now I have no intention to-night of trying to explain how all this can be done, because we are fortunate to have in our midst not only the Chairman of the Departmental Committee on the Teaching of English, but other members who will tell you with far greater authority than I how this highly desirable reform may be brought about.

I will now pass to the second part of my paper which is very much shorter and which deals with the need of an institution of higher education where speech in all its developments can be systematically studied and a standard as it were main-

tained, and which might provide training not merely for budding actors and teachers, but also for barristers, clergymen and others who wished to take a course in one of the principal branches of their craft.

You will not, I hope accuse me of wanting to make teachers "stagey" or train clergymen to speak like tragedians, though I am not sure whether the pulpit would not in certain cases be the gainer. The courses would naturally be planned to suit the needs of the different types of students.

One only wonders why the need for such a school has been so long in making itself felt. The present apathy is probably due to the fact that the old teachers of elocution, while necessarily empirical, enunciated their rules of thumb as if they were infallible dogmas. They were chiefly concerned in trying to turn out people who, having lost the major part of their personality in the process, were more or less inferior echoes of themselves, a fault not confined to teachers of elocution. You may, in fact, divide up educationists into those who desire to remake the pupil in their own image and those who wish to give creation a chance. Be that as it may, the deadly uniformity they produced has led to a reaction against all training. Yet a person properly trained, so far from losing his personality, should find that the course of training he has undergone has evolved in him an organ to play upon and express his emotions, in a word a body ready and able to vibrate to the commands of the soul. So far from being an animated phonograph or mere barrel organ, reproducing the mechanical effects of his teacher, he has developed himself as an instrument to express his own originality and that of others.

Does such a school already exist? It does, to a certain extent, in the Central School of Dramatic Art, which is at present housed in the Albert Hall, and which has been largely built up by the devotion and loving care of Miss Fogerty and Dr. Aikin. The mere recital of the subjects on its programme will give some idea of its scope. There are complete courses for men and women students in Dramatic and Stage Training and in the teaching of speech for teachers as well as remedial courses for speech defects (stammering and the like), practice classes in public speaking and debates and single courses in recitation and voice training. It is no mere culture in "*vox et præterea nihil*," but all the

physical and mental aids to perfect speech are enlisted, such as dancing and fencing on the physical side, and severe intellectual study of the passages for recitation on the mental. A similar training on more directly specialised lines is given for those intending to enter the theatrical profession by that young and vigorous institution, the Royal Academy of Dramatic Art, at which the L.C.C. have just established two special Dramatic Scholarships, the first public recognition, one believes, that the profession has ever received.

What these schools and others are doing is excellent, but is it enough? Can one say that the status they occupy in the educational hierarchy of the nation is really adequate? Is not the moment at hand when they should be definitely recognised as an *integral* part of a national system? Certainly, apart from the epoch making report I have just mentioned, there are many omens which seem to indicate the growing opportuneness for such an incorporation. To mention only a few. The increasing importance assigned to the spoken word in the schools of the nation, the renaissance of the dramatic art in the schools themselves and in the country at large, as evinced by the school plays at Gresham School, the Elizabethan productions at Avery Hill and Birkbeck College, the Repertory Theatres, the Stago and Phoenix Societies, the British Drama League, and those numerous bands of village players springing up through the countryside; the rising standard demanded from lecturers, clergymen and public speakers; the foundation by the Poet Laureate of the Society for Pure English and the gradual rehabilitation of rhetoric, so long under a cloud, and last, but not least, the growing conviction that acting, like journalism, is a profession and must benefit by a professional training.

How, then, is such an incorporation to be attained? By the creation of a special faculty in the University, in which speech is studied as a main subject by those intending to go on the stage or as a subsidiary subject in varying degrees by those who are proposing to enter politics, teaching or the church. Such a faculty should work on the one hand in close accord with the phoneticians on the practical side of their work, and on the other with the teachers of music, if, indeed, the latter should not, though already occupying separate institutions of their own, be united as constituent

colleges in a conservatoire of national standing, of which the two institutions mentioned above would also be partners. Too long have the arts and crafts been divorced in this country from our higher literary scientific and technical studies, and their fruitful inter-action thereby largely minimised. Yet who will deny that even in so abstract a subject as mathematics some of the clarity and artistry of expression that distinguishes French mathematical work is not directly due to the artistic and literary milieu in which even French mathematicians are brought up, whether as students of the *École Normale* or as members of ordinary society? Again, the influence on the arts of the more technical subjects, like engineering and building, is still more patent. It is true we are only dealing here with Diction, but its direct effect on the appreciation of literary work and of composition and essay writing is equally obvious. Everything, indeed, seems to point towards the eventual recognition of a faculty of Diction, whose constituent colleges should be united with the present colleges of music in a national Conservatoire, the whole thus forming part of a national University.

Perhaps some of you may think that the creation of such a faculty is not a matter of immediate realisation, though for my own part, I am convinced that in the long run it is absolutely inevitable. In any case, I believe that a practical beginning towards such a desirable consummation might be made at once by the University establishing a diploma in Dramatic art, as recommended by the Departmental Committee in English. There is already a precedent in the diploma in Journalism that has recently been established. Moreover, it is only a matter of time (and I would add money) before we see the setting up of University Chairs and scholarships in Dramatic Art such as exist in several American Universities. Liverpool, indeed, has already made a start by appointing Mr. Granville Barker to such a chair.

May I add, in conclusion, one word to emphasise the intellectual element in acting, which the "natural" school seem to ignore?

Acting, of course, is not predominantly an intellectual art. Temperament is a *sine qua non*, but the finest acting is temperament enlightened by intellect. In spite of the advocates of "naturalness," the real leaders of English acting, the

Granville Barkers and Nigel Playfairs have by precept and example shown the importance of the intellectual element in acting. You cannot interpret an author with ideas unless you have the trained brain to understand him. Again, we have only to look across the water to see how seriously the best actors take their profession, especially those who have been pupils of the Conservatoire, which serves as the *École Normale* of the *Théâtre Français*. I am not going to enter now into the defects of this institution, its non-connection with the University and the need of making its instruction more synthetic, I will merely say that so far from such an institution turning out budding actors who think they have nothing more to learn, the exact opposite is the case, as may be seen from a Sarah Bernhardt and a Guitry. I was informed years ago by one of the members of the Bernhardt family that after creating a part, Sarah would, during the whole run, spend several hours every day in sheer hard thinking and experiment, with a view of perfecting her role, and for aught I know, she does so still. Again, only recently I was told of the two Guitrys, when they were over here, that father and son are perpetually rehearsing at any odd moment that occurs the particular parts they are playing, in order to perfect some portion or point that did not seem to go well the day before or which they think they can improve. This is the secret that lay behind the extraordinary effect they produced on the audience in such a play as "*Mon père avait raison*." Speaking for myself, as a mere amateur, I can only say that the first act absolutely thrilled me. I do not think I have felt anything like it for twenty years. One was at once enthralled by the supreme illusion of life they produced, and at the same time transported by the perfection their technique attained. It was a triumph for the conservatoire tradition, "*de l'effort et toujours de l'effort*," and an object lesson of what a similar conservatoire might do for England.

DISCUSSION.

THE CHAIRMAN (SIR HENRY NEWBOLT), in opening the discussion, said the first windmill which the author tilted against was the school of naturalists—those who told people they had only to be themselves, to be natural—and it was perfectly true that the last thing

anyone would wish an Englishman to be upon the stage was natural. That was a fact, neither complimentary nor uncomplimentary to English people: it was merely a candid and scientific description. As the author had said, when an Englishman thought he was behaving naturally he was either not behaving at all or behaving with a curious abrupt kind of brutality. What was meant by the word "natural?" Man was not merely an animal; he was, of course, fundamentally an animal and had a basis of animality, but when one said that a certain thing was "natural" to man, *i.e.* highly characteristic of man, one did not refer to that part of him which was purely animal. Now all animals had a behaviour which was natural to them and nobody would dream of criticising it; the natural behaviour of an animal in any circumstances was always simply unconscious ease and, according to its own shape and habits, it was graceful. If man were merely an animal he also would invariably move about easily and gracefully and, in a sense, perfectly, whereas in this country at any rate the exact contrary was the case. It was clear then that man was not primarily an animal. Man was primarily a human spirit; the human spirit had been placed in the body of an animal, which did not belong to him and was an exceedingly uncomfortable suit of clothes in which he had to go about for the whole term of his natural existence—in many cases in this country it resembled a strait waistcoat. If, at an age when he was still unconscious, a man had been put into shackles, into an iron mask and a strait waistcoat, in which he could not move as he wished and in which he could not express himself, what would be that man's natural desire? Surely, first of all to discover some means of freeing himself, at whatever cost of labour and experiment and however gradually. That was exactly what had to be done in education. The human spirit wished to be free, but it could not be free until it had acquired that which the author had called a technique of some kind, or, in other words, some knowledge of an art. Nothing would set any human being free except a share in some art; nothing would set an Englishman free in the first and most important way, but some share of the artistic in the way in which he handled his own language, and, secondly, something in the way of manners, *i.e.*, the artistic way of handling the movements of his own body. A very famous Frenchman once said: "Man is always born free, but we see him everywhere in chains." He would maintain, on the contrary, that man was everywhere—in this country, at any rate—born in chains, and he could not be seen properly nor could he realise himself until he was set free, and the only way of setting him free was by some tincture of some kind of art. The author went on to propound a theory of what he called inspiration, that there was something necessary to the action of genius which might be called

"taking pains," taking pains in the acquiring and in the exercise of that technique which was so desirable. Personally, he would use the word "Inspiration" for something which came after that, something which was added, something which was not necessarily drawn only from the generalised experience of the race to which he attributed it, but also came from the power of being able to draw upon something rather deeper than the experience of the race, something of that spiritual life which lay underneath the whole race, and which was available at certain times when a man who was working was able, as it were, to put down his pump and bring up something for his own use. Personally, he believed that the secret of all art was that that so-called inspiration, those moments of greater power which came to a man, as it were, from outside, were invariably given to him by accident and that no amount of endeavour would ever succeed with any man in creating one word or one line or one drawing of inspiration of any real original genius, but that when he was doing his best to set himself free, to move as his spirit wished in the sphere of his own art, there would be added unto him something more, something which was quite as much a surprise to him as it could possibly be to his readers or to those who saw his pictures or heard his speeches. If that was the author's meaning, then he could say not only that he agreed with it himself, but that it was in accordance with all the highest authorities in the art of which he had some small knowledge, namely, the art of literature. All those authorities, from the Elizabethan period onwards, were agreed that there was such a thing as a contribution from beyond and outside man's own will, and that he obtained that not by waiting idly for it, but by doing his very best and working his very hardest along the lines of the best technique available to him. The author went on to touch upon the very different state of affairs existing in the French and the Italian nations, and said that to the Frenchman and the Italian expression by gesture and in a ready and appropriate form of language was native. That was certainly true; there was an immense gulf between those people and ourselves, and that he attributed to a difference in time. English people were the product of a very much more recent civilisation. The French and the Italians had inherited, from a civilisation whose antiquity compared with our own was almost incalculable, a freedom to which only a very small number of English people could attain, and then only at the end of a long life. It was probable that in the mere use of language the best writers in English did attain a freedom which was comparable to that of the Italian and even, in a few cases, comparable to that of the Frenchman. It would be noticed, however, that the more perfectly a man wrote or spoke English the more he admired the exquisite instrument of the French language, which was

another way of saying the exquisite precision and delicacy of the French thought. In the matter of gesture, he thought it would not be going too far to say that, with the exception of a very small number of our most distinguished actors and actresses, English people never acquired it at all. There was no reason why, if the French had taken thousands of years to attain that freedom, we in this country, having awoke to our necessities, should have to wait thousands of years before we attained it ourselves. It was possible to learn much more rapidly when one had a vivid example before one and had the will to learn. It was for that reason that he, personally, welcomed the author's suggestion that we should keep a very close observation on our neighbours across the Channel. The author had touched upon another point closely connected with that, the question of rhythm, and he thought that rhythm entirely bore out the author's main argument. Rhythm was also natural to man. Children could be taught to acquire very quickly a taste for rhythm, either in words or in movement, because rhythm was one of the secrets of human life. He did not know why it was so, but there was not the slightest doubt that rhythm was the nearest approach in this world to what was called magic. When the effect of rhythm on the communication of ideas from one man to another was considered, its value would at once become evident. He remembered that when he was an undergraduate at Oxford, a Greek play was acted in the University of Cambridge, and a friend of his, who knew no Greek, was cast for a part, because, owing to his gigantic stature, he was more fitted for it than anyone else. He spoke his part in Greek, the words having been written out for him in English capitals, and he having learned them by heart. When the performance of the play took place, those amongst the audience who knew very little Greek did not notice that anything was wrong, but the scholars who were present detected the fact that what his friend said was quite unintelligible. He pronounced every vowel and consonant as he had been told to pronounce them, and the result was absolute gibberish. Quite apart from whether a man understood what he was saying or not, the effect of the rhythm, the effect of what might be called the sound of the meaning, in English prose and in English poetry was of greater importance than anything else. The beauty which was so inexplicable in the best English poems, was not the beauty of the sound as measured by consonant and vowel, nor was it the beauty of the sound as measured by the strict metre in feet in which the lines were written; it was the beauty measured by the sound of the meaning. A writer might produce something which was perfectly correct and expressed his meaning perfectly and yet, although it was written in a poetical form and even expressed a poetical sentiment, it might not be poetry at all, because

the sound of the meaning was against it. He remembered a poem published in a New Zealand paper thirty years ago, a poem written with very sincere emotion on the death of a favourite preacher, the Rev. Mr. Kelly, and the last stanza of that poem had remained in his mind ever since. It was a serious elegiac poem, perfect in diction and in metre, but the last verse was as follows:—

“How well he loved in colours warm
To paint yon City fair,
Even it has now an added charm
With Mr. Kelly there.”

Whenever there was an intonation in any form of verse which had the sound of a meaning which was argumentative or a definite statement or in any way prosaic, it did not matter what the outward form of the verse was or what the sound of the syllables was—the sound of the meaning was not poetical and therefore there was no beauty in the poem. In Milton's beautiful hymn on the Nativity there were curious lines which always haunted the reader, although they appeared to have nothing but plain prose in them:—

“The shepherds on the lawn,
Or ere the point of dawn,
Sat simply chatting in a rustic row.”

Anybody would say that “chatting” was a highly prosaic word, the word “simply” was almost slang, and “rustic row” was very ordinarily alliteration, but that line in that stanza had an extraordinary charm which had lasted for three hundred years.

The last and most important part of the paper was that in which the author spoke of the necessity of something being done in this country for speech training and the method of doing it. The necessity would probably be admitted. There was one reason for that necessity which the author did not mention, namely, that speech was of all the arts the one most essential to man, because the life of the mind could not exist apart from speech. A critic in the “Spectator” who, he thought, was rather more anxious to make a point which nobody else had made than to put forward a very serious proposition, criticised the report of the Committee on the Teaching of English by saying: “There is not one word from beginning to end of these four hundred pages which can show that the Committee have ever given a moment's thought to the question of whether there might not be found some other fundamental basis for English education rather than the English language and literature. Why, for example, should not music be the fundamental basis of every child's education?” The answer was of course obvious. Music was very valuable, but before one could do anything else in the way of living one must begin to live by communicating with other human beings, and language, not music, was the method of communication. The result was that until one could use the three

hundred words that the inhabitants of Suffolk used to be content with in a better way than merely saying Yes and No, one was not fit to take one's part in a society, and a society was not only the end of man's existence but was the only means of his existence as man. There was no doubt that the Latin civilisations were based upon that principle; it was their history, their justification and their glory. It was only necessary to walk into an Italian or French town and listen to a conversation between two of the inhabitants to see the whole of their life and to realise that they were a society and had been a society from time immemorial. The result was that which he had already stated. If English people were to attain to anything of the same kind they must not only have lessons but actually practise the art of life. They must be urbane; they lived in cities so why should not they behave as if they lived in cities? They did really desire to know each other and to know themselves. Personally he fully believed in the desirability of establishing a Conservatoire, and he had seen some teaching in London which was of especial value, such, for instance, as that of Miss Fogerty, who had achieved a miracle and achieved it so perfectly that her pupils appeared, after a very short training to be literally acting and speaking with perfect naturalness, a naturalness which was the result of the extreme perfection of the teaching they received. Quite apart from that, he thought it was very desirable that all over this country those who taught anything anywhere should be in very much closer intimacy with one another and also with other persons who were not teaching but were likely to belong to that body of citizens who it was generally agreed were the only arbiters of such things as pronunciation. Wherever one went in English society one found sects slaughtering the English language by mispronouncing it. He believed, however, it was agreed by every authority that there was only one standard of well-spoken English and that was the standard of the "best society." What the "best society" was one need not enquire; it certainly was not any society that could be named. He did not blame the teachers, because they had not the power of taking the initiative in the matter, but he blamed the inhabitants of this country belonging to what were called the upper classes or the educated or cultivated classes, because they did not often enough include amongst their friends and amongst their guests the teachers who lived near them. A very distinguished man, a Cambridge scholar and a Judge, had said to him that day, when speaking of the English teacher, "It is unfortunately true that, although we cannot afford it, we must pay our teachers highly because nobody in England is estimated socially by any other standard than the amount of his screw. If we do not pay our teachers better than policemen you cannot expect people to think much of them, and that is why it has

been necessary to raise their salaries. The moment it is ascertained that a man or a woman is a teacher, he or she becomes a cipher and ceases to count in the social system." That was the national failing of this country and it was the one real kind of snobbery which existed amongst us, the snobbery of thinking that material welfare and wealth were the measure by which not only to appreciate ourselves but to depreciate those whose intellect and education were often superior to our own. The work of teachers should be recognised not only by giving them higher salaries but by honouring in every way those activities towards which teachers were leading: for instance, not to speak of children's time being wasted or the taxpayers' money being wasted by the children being taken to see Shakespeare's plays, but honestly to believe that they went there for much the same reason that other people went there—for that intellectual enjoyment which was one of the highest functions of life.

MISS ELSIE FOGERTY said she was an Irish woman who had been to a great extent educated in France and was fortunately bi-lingual. A great part of her training was carried out under the aegis of the wonderful Conservatoire to which the author had referred, and she hoped that a similar one would be established in this country, but on the present occasion she wished to stand up as a champion for the dramatic gifts and possibilities of the English people. It must not be imagined that, because the people of other lands had a certain external facility in outward expression, that was necessarily the right and proper way for the people of this country to express themselves. She felt that an English audience deserved most of what had been said that evening and that our level as a nation was low, but she did not believe that we were behind in genuine dramatic expressiveness. Perhaps she might claim to know a little about the subject, because she had taught people of three nationalities. She once went to a small German town, where she was enormously impressed by the vivid expressiveness of the tragedian of the evening. The next day she lost her trunk and the station master acted in exactly the same way, and she did not feel quite so much respect for the tragedian's expressiveness after she had seen the station-master tearing his hair on the platform. It seemed to her that in art levels of tone were the real question; not whether one had attained the highest possible degree of power and intensity but how completely one had measured the degree of variety that one obtained. She would be glad if the author could give a rather more fundamental view of what rhythm was. It had been said that rhythm was near, to life, but she thought it was more than that and that rhythm was the fundamental law of movement, exactly as gravity was the fundamental law of stability. Rhythm was really the synchro-

nising of time, of force and of space under the direction of intention; the English feeling for rhythm was almost the strongest in the world. In proof of that, she would urge the capacity of English people for games and also the fact that their poetry was less metric and more rhythmical than that of any other nation. After all, had they really failed in that side of art? Surely the language, the training, the achievements which had given the English people their literary history from Chaucer to the present day could not be accused of any lack of that essential and fundamental sense of rhythm. What the people of this country must be criticised for was exactly what the Chairman had mentioned—a certain fundamental scorn for artistic expression. The greatest service that a Conservatoire would render to this country would be to give back to the people more of their heritage of freedom. Though it was quite true that Garrick said that French actors exaggerated, yet Talma, one of the greatest actors of the end of the eighteenth century, who founded so much of the quiet, reserved greatness of French acting, himself learned a good deal from Garrick. She believed the English people had an infinite capacity for dramatic expression, but that they must find it in the genius of their own tongue. They had to speak the flexible, free, five accent rhythm of blank verse, which was never equal in its two halves, whereas in France they had the Alexandrine metre and thus had a stricter, a more regular and a more metric problem than the rhythm which was required in such lines as: "Ye elves of hills, brooks, standing lakes and groves," with their wonderful median pauses. She thought the people of this country should not disparage their own dramatic and rhythmic gifts.

MR. GEORGE SAMPSON said he wished to emphasise, from the point of view of a school-master, what had been already said. It was just 52 years since the first Elementary Education Act was passed in this country, and now the axe had been laid to the root of the whole system. His school happened to be in the neighbourhood of Sloane Street, and he heard a good deal of what might be called the Lowndes Square view of life. On the previous day he had been talking to a lady about the "cuts" in education, and she said, "What we have to give the children of the working classes is a good plain practical education with no trimmings." He asked her to explain what she meant by "trimmings" and she replied: "Music, literature, and all that sort of thing." Again, the Member of Parliament for his own constituency said recently: "What is the use of our giving everybody an education? After all, there can be only one Lord Chancellor," and there was the now immortal Alderman McArthur of Cambridge, who asked, "What is the use of education to a man who is going

to hold the plough or to spread manure?" Questions like that really went to the root of the whole matter. What were we trying to do in the schools? Were we trying to make education a contribution merely to those hours of a man's life which were not his own, which he sold to someone else, or were we trying to make education a contribution to the whole time of a man's life? That was a question about which we must think seriously. Speaking as a school-master, who had worked for 27 years in different parts of London, he could say that he was still an optimist. He believed that a teacher must very often turn his eyes away from the factory and the workshop and look in the direction of the City of God, and see before him, when he looked at his assembled school, not so many heads to be stuffed but so many souls to be saved. He would find his school to some extent a collection of inarticulate beings and the beginning of their education must necessarily be in their language, which was their tool and the instrument for everything they would have to do. The beginning of language was obviously speech, and the beginning of speech came at a very early age. Speech training, as the author pointed out, could not begin too early. How little used to be thought of speech training could be gathered by the fact that his own education as a teacher took no notice of the subject at all. There had been an improvement since that time, but even now the position in regard to that matter was not nearly as good as it should be. One thing that teachers lacked was a standard, as the author had said; they did not know where to look for their standard speech. They could not look to the stage for it, as in France. The foundation of national speech must be laid in the school. Exactness of speech was not a trimming, it was not a mere negligible extra in the school of life. It went down to the root of the whole matter, because the different classes in this country spoke different languages. The country was sundered by chasms across which the classes were glaring at each other almost with hatred, and that hatred would deepen and those chasms would widen as long as the speech of the classes was different. An endeavour must be made to teach the children in the schools standard English. Although it was difficult to say what standard English was, teachers knew what was not standard English; as a rule they could tell a broach of standard English when they heard it, and he thought for them that was a sufficiently good working basis. There was another way in which the speech of the country could be improved, *i.e.*, let the Board of Education insist that in all the schools of this country some approach to standard English should be required. By that means, standard English would not be obtained in a generation, but an effort would be made in the direction of obtaining it. He believed very firmly that to teach children to produce correctly the sounds of the words they

used and to approximate their speech to the normal speech of this country, was really not an educational fad but a great social remedy.

MR. KENNETH BARNES said he agreed with nearly everything the author had said, but he felt there was a danger of separating speech from thought. The only speech that was worth anything was that which expressed a thought, and nobody could be said to be really eloquent unless he had behind his speech a live idea. The disadvantage of speech training was that it sometimes gave the pupils the idea that there was something in the actual speaking of the words that made them charming. It was most important to realise that words were, so to speak, current coin; they were not of value in themselves. With that restriction, he felt that all the author had said was true. The children in the schools must be taught how to speak so that they would grow up with the right tradition of English speech, and then when they left school they would not need the very special training that they required at the present time if they were to speak well. He thought that, until there were sufficient teachers to teach those children in the schools, some movement to obtain a special class of teacher for the schools would be a very good thing. The subject in which he was interested was the drama, and he wanted people on the stage to set a right example in their methods of speech. At the Institution of which he had the honour to be the Director, everything possible was done to ensure that. There were many difficulties. Very often a student who had been well taught in a school would be mismanaged by a stage manager, and on the stage people had to do all kinds of things in the way of spontaneity and so forth which they had to make appear natural when they were not natural. There were, therefore, many complications in regard to speech training for the stage, perhaps more complications than there were in regard to speech training for public speaking. His Institution was doing all it could to raise the standard in that direction and he hoped it would be successful.

MR. W. SHARMAN (President of the London Teachers' Association) said he thought the author had dealt with the subject so well that there would be general agreement with the statements made in the paper. Speaking as a teacher, teaching working class boys, he wanted to thank the Chairman for what he had said that evening, and also for what had been said in the Report of the Committee on the Teaching of English, that the boys in the poorest schools had a birthright in the English language.

DR. W. A. ATKIN said that many years ago he was struck by the fact that there were so

many different opinions as to what was good speaking and what was not, that he determined to set himself the task of doing all he could to elucidate the matter, and he came to the conclusion that, from what was known of physiology and psychology and the laws of sound and the laws of voice, a general principle could be framed by which people could be taught to speak. Twenty years ago he had the privilege of speaking at a meeting of the Society of Arts, on the subject of phonology, which was something more than phonetics or mere pronunciation or inflection and dealt with the humanity of the voice, that which spoke as the utterance of the individual. After a number of years of teaching, he found that the best thing to do was to supply the individual with a really phonological control over his powers of making sound. He quite agreed with Mr. Barnes' remark that every speech should represent a thought, and what could be done in training was to supply each individual with the instrumental faculty of making sounds that might express his thoughts. That was what the Central School of Speech Training was trying to do—to give its pupils instruments upon which they could play their language, including what their own emotions and thoughts and imaginations might provide, as well as the general inflection of the voice and the proper pronunciation. He felt that the School had already made great progress. It was only by education that people learned to use correctly the vocal instrument in the faculty of speech. No one spoke naturally; speech was a thing that had to be learned laboriously in early years. If people learned to speak properly so that they made the most of the sounds they were capable of producing, then pronunciation came as the refinement of speech. Pronunciation was not the important thing; the important thing was that each individual should be able to express himself or herself in sound to the ears of other people, so that they might communicate their thoughts, whether their own thoughts or the thoughts of the great dramatists whom they at the moment represented. There were now general principles; there was a standard not of speech or pronunciation, but of voice use, a standard of instrumental efficiency by which each individual could make himself or herself understood.

MR. J. W. SAMUEL said he wished to express his gratitude to the author for what had been said in the paper. He thought it should be realised that those who taught in primary schools had been stifled for years by Departmental prescription and those who taught in secondary and high schools had been fettered for years by the stupidity of the classical tradition enforcing its rules upon a language it should not be allowed to govern. It was only within the last few years that teachers had been

relatively free to handle English in the way in which scholarship and investigation showed that it should be handled. He was glad to take the present opportunity of saying that, in so far as the Report of the Committee on the Teaching of English was an expression of the newer order of things, and an indication of the way in which that newer order of things was to be developed, the teachers of the country were greatly obliged to the Chairman. Efforts towards the establishment of a Conservatoire and the other steps mentioned in the Report were bound to multiply and out of them much good would come.

MR. CLOUDESLEY BRERETON, in reply, said he was very grateful to the Chairman for having raised the question of inspiration and technique. Evidently he had not made himself quite clear, for his point was that technique was, as it were, a sort of training, and it was only when one was really trained that one could run the race of inspiration. With regard to cultured speech, that was an extremely thorny subject. Personally, he did not think that the most cultured speech was always found at the top of English society, in fact, if the speech of that class of society was analysed it was found that from a phonetic point of view it often left much to be desired, but it was a very good instance of how intonation compensated for that. He thought a standard of Southern English might be obtained. People from Scotland thought that those who lived in the South spoke a very debased dialect, but the latter were in such a great majority in England that they could afford to treat that accusation with more or less complacency. There was one thing, however, which was done in France and which he thought might possibly be done in this country, *i.e.*, to obtain something like a standard pronunciation for the training colleges. In France there was no attempt to stamp out local dialects, and he was sorry that more was not done in this country to preserve dialect, but what was done in France was that the teachers in the training colleges were taught a standard French which they taught the children. It was very important that if the children in France moved from one Department to another they should be able to make themselves understood, the dialects in France being even more different from one another than was the case in this country. He was very grateful to Mr. Barnes for bringing out the point he tried to make at the end of his paper about the necessity of cultivating the intellectual side in acting, which was another way of saying that speech without thought was of little value. There must be hard thinking before a person could really give the right intonation and speak his lines in the right way.

On the motion of THE CHAIRMAN, a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting then terminated.

CHOTA NAGPUR AND ORISSA

The province of Bihar and Orissa falls into two fairly well-defined parts—Bihar, and Chota Nagpur and Orissa. The geographical division between the two does not quite follow the political boundary; but the contrast, for all practical purposes is complete.

Bihar proper is a purely agricultural tract, which, except on the northern and southern borders is an alluvial plain. Every available acre is cultivated by the teeming population, and save in Purnea and Champaran, there is little or no forest and hardly any pasture land. The industries are based on agricultural products or the needs of agriculture, the chief of these at present being sugar-making, oil-pressing, indigo manufacture, and the production of saltpetre and sodium sulphate. Others of importance that may develop in the future are tanning, jute and linen manufacture, rice hulling and the production of fertilizers.

Chota Nagpur and Orissa have a very different future, and practically the whole area is an undulating laterite formation. Of the total area of 69,468 sq. miles a large part is under forest; the bulk of the population is without labour prejudices, and, it would seem, expressly planted there by Providence for the development of the mineral wealth of this tract.

Large portions of the area are as yet without railways, there are few roads and the main rivers are only navigable for a portion of the year. The Orissa coast tracts are traversed by the main line to Madras, which has but one branch to the coast— and that to Puri where no harbour exists. The harbours of False Point and Chandbali, such as they now are, are not connected with the hinterland by rail, nor can they accommodate ocean-going vessels of deep draft.

This undeveloped country contains nearly all the coal and most of the iron ore located in India, besides other minerals such as copper, chromite, mica, limestone, manganese, monazite, graphite, bauxite, china-clay and fire-clay. Its main importance lies in its coal and iron deposits and their juxtaposition. Of the coal fields now worked, those in Bihar and Orissa yield nearly 70 per cent. of the total output of India; while if the Raniganj field is added, the production in the two provinces would amount to no less than 90 per cent. of the whole. The Jahria field alone produces over 50 per cent. of the coal raised in India; while the Bokharo mines, which are in process of opening up, will soon add largely to the total.

In addition to the existing fields, quantities of first-class coal have been located to the west. In the north and south Karanpura fields, huge deposits of coal are available, outcropping to the surface in thick seams. To the west again are the Aurangar and Hutar fields forming the end of a long chain towards the Daltonganj. To the north of Dhanbad is the small Giridih field, at present worked by the East Indian Railway and

producing some four per cent. of the total output of India, while far to the south lie the Hingirampur mines near Samalpur and the newly proved field at Talcher in the Feudatory State of that name to the north-west of Cuttack.

The important deposits of iron ore hitherto located in Chota Nagpur and Orissa are in the Kolhan sub-division of Singhbhum district and in the states of Mayurbhanj, Keonjhar and Bonai. The deposits of Badanpahar and Okampad are extremely rich, averaging over 60 per cent. of iron and in some cases as much as 67½ per cent.; but they are small in comparison with the vast deposits that have recently been located in the Kolhan and north Keonjhar. The north west corner of these deposits had been worked for some years by the Bengal Iron Co., but the quality and extent of the ore to the south was unsuspected. Recent discoveries have shown vast deposits of hematite ores in quality equal to the Mayurbhanj ores and in quantity only to be reckoned in thousands of millions of tons. The development of these ores and the linking up with the coal fields to the north, where coal suitable for blast furnace coking is available, is now in progress. Extensive limestone deposits, suitable for use as a flux in metallurgical operations, are found in Gangpur State to the west, close to the Bengal Nagpur Railway main line.

The Bengal Iron Co. have settled down to a solid prosperity based on the production of pig-iron and castings made from it. There are now five furnaces, four always in blast, with a daily output of 450 tons of iron. The iron foundries cover an area of approximately 120,000 sq. ft. and include pipe foundries, iron sleeper foundries and a foundry for special castings.

The well-known Tata Iron and Steel Works obtain their iron ore from Mayurbhanj, their limestone flux from Panposh and Raigangpur, and their coal from the Jharia and Raniganj fields. The plant at present consists of three blast furnaces, with a capacity of 900 tons of pig iron per diem, and seven steel furnaces capable of producing approximately 17,500 tons of steel ingots per month. In the rolling mills, steel rails, joists, angles, channels, tees, etc., are produced. Further extensions are in course of erection. Two more blast furnaces, capable of producing 1,000 tons of pig-iron daily, are nearing completion. Further, the erection of a plate mill has been completed.

Besides the two existing iron and steel companies, three more large concerns and one smaller one are being planned.

The only other metallurgical industry which seems likely to succeed at present is the production of refined copper. No attempt is being made to refine the chromite and manganese ores occurring in the district, although they are mined and exported, or else used as a refractory material. The main sources of supply for refractory materials, such as fire-bricks,

silica bricks, etc., are the north east corner of this area where the works of a number of concerns are situated. Another subsidiary industry is the production of coke in by-product ovens. A number of these ovens is now in existence at Jamshedpur and Giridih and in the Jharia coal-field itself. The total output of ammonium sulphate and tar during 1920 is reported to have been 3,720 and 8,880 tons respectively.

MANUFACTURE OF MILK PRODUCTS IN AUSTRALIA.

Although the manufacture of preserved milk and milk products is of relatively recent origin in Australia, the industry is now an important one. As it provides an outlet for the Commonwealth's great dairying and pastoral interests, a large local trade and a certain amount of export business has been built up. While a considerable part of the machinery in use is now being manufactured in Australia, the developing needs of the preserved-milk industry will require the latest and most scientific machines from abroad.

According to a report by the United States Consul at Sydney, the total present turnover of the principal plants in the Australian milk-preserving industry is estimated to be about 34,000,000 gallons of fresh milk, while the annual output of the factories during 1919 was reported to be worth £2,140,470. The amount of capital invested in the industry at June 30th, 1918, was £1,822,017, and about 3,000 hands were given employment. The existing factories are principally in New South Wales and Victoria, but others have been established in Queensland, where there should be good possibilities for development.

Up to about 30 years ago the condensed milk used in Australia came from Switzerland and the United States. Earlier attempts to establish the industry in Australia were not uniformly successful, largely because of defective manufacturing methods. The past three years, however, have seen great advances, and in one product—sweetened condensed milk—the Commonwealth is now on a sound and successful producing basis. By degrees the manufacture of other milk products—concentrated milk, unsweetened condensed milk, dried (or powdered) milk, lactose and lactogen, and infant and invalid foods—has been undertaken and made very satisfactory progress.

There are three or four Australian factories at present manufacturing dried milk on a large scale. Since they are operated in conjunction with other branches of the milk-preserving industry, the output is not known, but the consumption of dried milk is rapidly increasing, and the demand shows signs of further extension.

Before the Great War lactose was imported from the Netherlands, but a large factory for

its manufacture is now in operation in western Victoria, with a producing capacity equal to all local needs.

Infants' and invalids' foods are now being made in Australia, corresponding in their composition to most of those imported. This is the newest and smallest branch of the milk-products manufacturing industry, and it will prosper if local preference for the imported article can be successfully overcome.

The following are the official figures, covering the fiscal year ended June 30th, 1920, for the production of condensed and concentrated milk and other milk products:—New South Wales, 12,969,679 pounds; Victoria, 44,219,389 pounds; and Queensland, 9,170,034 pounds. (The Queensland figures are for the calendar year 1919.)

USE OF TRACTORS IN PERU.

The increasing importance of tractors in Peru may be best realised by comparison of the number imported up to 1919, which was 382, with the number imported during the first four months of 1920, which was 271. At present, writes the United States Trade Commissioner at Lima, there are in Peru nearly all types of tractors—European as well as American. There seems to be a marked prejudice, more among dealers than buyers, against tractors of the caterpillar type. However, it is interesting to note that in the northern region of Peru, in the neighbourhood of Paita, where the soil is sandy, the wheel type tractors have been unable to produce results, and a number of small tractors of the caterpillar type are in use and working very successfully.

In Peru, sugar and cotton are not replanted each year, one planting carrying through for several years. The land requires cultivation, however, for while it is fertile it is inclined to harden, and thorough breaking is necessary occasionally. This hardening is inevitable in the case of irrigated lands, such as are all farm lands on the west coast of Peru. Therefore, the question of service is a very important one in these irrigated districts. Every farmer usually has a certain fixed amount of water available each year, and the practice is first to irrigate the field before ploughing. If the tractor breaks down just at the time when he has the field irrigated, and he is unable to get the service that will enable him to place his tractor in working condition within a reasonable time, he is in great danger of losing the use of the field for the season. If the land is ploughed while dry, it is likely to break up in large lumps, making it very difficult to prepare the proper seed bed. One reason why tractors are so popular in the irrigated district is that a farmer is enabled to work his land more rapidly than by the use of the animal power, thereby conserving moisture, and since the use of water is

restricted, he can by this means work more land with the same quantity of water.

In cultivation, the rows are planted 1.3 metres apart, so it will be seen that the tractors to meet this demand should be of the gauge indicated. A tractor, especially a cultivator, that can straddle a row is particularly desirable. Thus one with a bottom clearance of 20 or 24 inches, or more if practicable, could cultivate both sides of a row at once, even after the sugar or cotton had reached a height of 3 feet or more. As to the size of tractors most in demand, the small 2 or 3-plough tractor, commonly known as the "12 to 20 horse-power" is most in demand, and probably 90 per cent. of all the tractors imported into the country are approximately of this size.

GENERAL NOTES.

THE YIELD OF EGYPTIAN COTTON—In the current number of the Bulletin of the Imperial Institute, Mr Gerald C Dudgeon, C.B.E., lately Consulting Agriculturist to the Government of Egypt, discusses the causes which have led to the decline in the yield of cotton in Egypt. Whereas during the six years ending 1899 each acre under cotton produced on the average an annual crop of over 500 lb of cotton, during the eight years ending 1913 the average yield had fallen to just over 400 lb, and in 1920 it was as low as 320 lb per acre, the reduction in 20 years thus amounting to 36 per cent. Such a decline, if not checked, must in time have a serious effect on the prosperity of Egypt, which depends so largely on the cotton growing industry. It is pointed out that although the chief causes to which the decline is due have been recognised, the proportionate share of each in the result is often so unduly emphasised as to produce a misleading impression, and this is apt to lead to the adoption of incorrect procedure. In the article in question, Mr Dudgeon places in their true perspective the different factors involved, such as the degeneration of the productive powers of the soil, the ravages of insect pests, and agrarian disturbance. He considers that great improvement would result from the completion of the comprehensive drainage scheme which was inaugurated by the indefatigable energy of the late Lord Kitchener, but was delayed by the War. The same number of the Bulletin contains several other interesting articles, in one of which an account is given of the tall grasses ("giant grasses") occurring in various parts of the Empire, and of the possibilities they offer for the manufacture of paper. Other articles deal with insects which are liable to cause damage to raw cocoa when stored in large quantities, and with the characters and uses of certain New Zealand timbers which are at present little known in this country.

TIMBER RESOURCES OF THE BELGIAN CONGO.—On many occasions, writes the United States Consul-General at Brussels, attention has been called by the Belgian Ministry of Colonies to the richness of the forests in Mayumba, in the Belgian Congo. The richness of these natural resources was really revealed during the war, when it was impossible to buy from Europe the barrels necessary for palm oil. The native woods had to be utilised and thus became known and appreciated, especially for the above-mentioned use. There has been considerable development since then, and now barrels manufactured in Mayumba are well prepared, perfectly tight, and can be compared with the European article. Cabinet wood also is now extensively exported. The attention of the exporters has, however, been drawn by the Belgian authorities to the fact that the exploitation is effected too rapidly, the raw timber not being allowed to dry sufficiently. The value of these woods is shown by the kinds currently exported, among which should be mentioned mahogany, designated by the natives under the name of "kilungi" or "kalungi." The "kambala" wood, which can be compared to oak, is dark yellow when cut, but rapidly becomes chestnut brown, similar to old oak. The "sangamenga" wood, of a brown red colour, which can be very finely polished and is equal to walnut for cabinet-making, is beginning to be utilised. Although the district of Mayumba is not well situated for forest exploitation, the exportation of fine wood is remunerative. The expense of exploitation is very low, and transportation and other charges to Antwerp are reasonable. The various other products obtained and marketed in connection with forest exploitation also contribute towards the general expense.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 p.m. :—

MARCH 22.—PROFESSOR A. P. LAURIE, M.A., D.Sc., F.R.S.E., "The late Mr. Holman Hunt's Experiments on the Permanency of Oil Colours." SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., in the chair.

MARCH 29.—SIR THOMAS OLIVER, LL.D., D.Sc., M.D., F.R.C.P., "Alcohol in Relation to Industrial Hygiene." (Shaw Lecture.) SIR ROBERT ARMSTRONG-JONES, C.B.E., M.D., F.R.C.P., in the chair.

APRIL 5.—PROFESSOR ERNEST R. MATTHEWS, "Coast Erosion and its Prevention." LORD HEADLEY, M.Inst.C.E.I., in the chair.

APRIL 26.—JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry."

SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the chair. Dates to be hereafter announced :—

MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work."

LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

PHILIP SCHIDROWITZ, Ph.D., F.C.S., "Recent Developments in India Rubber Manufacture."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock.

MARCH 24.—PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "The Indigo Situation in India." SIR THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., in the chair.

APRIL 28.—F. G. ROYAL-DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the chair.

MAY 26.—PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow, Magdalene College, Cambridge. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced :—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION

Tuesday afternoons, at 4.30 o'clock.

APRIL 4.—LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, G.B.E., K.C.M.G., "New Zealand." COLONEL HON. SIR JAMES ALLEN, K.C.B., High Commissioner for New Zealand, in the chair.

MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E., "Tanganyika Territory (formerly German East Africa)." Date to be hereafter announced.

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETING.)

Friday afternoon, at 4.30 o'clock.

MAY 5.—PROFESSOR WILLIAM HENRY ECCLES, D.Sc. (London), F.R.S., "Imperial Wireless Communication."

CANTOR LECTURES.

Monday evenings, at 8 o'clock.

GUY RADCLIFFE, M.Sc.Tech., F.I.C.,
Lecturer in Applied Organic Chemistry,
College of Technology, Manchester. "The
Constituents of Essential Oils." Three
Lectures. March 20, 27, April 3.

Syllabus.

LECTURE I.—MARCH 20.—Historical Intro-
duction. Geographical Distribution of Essential
Oils. Methods for Extracting Odorous Oils
and Floral Perfumes.

LECTURE II.—MARCH 27.—The Classification
of the Constituents of Essential Oils. The
Cyclic and Olefinic Terpenes and their more
important derivatives.

LECTURE III.—APRIL 3.—The Derivatives of
Benzene. Alcohols. Acids and Esters. Aldehydes.
Phenols and their derivatives. Heterogeneous
Compounds. The Trend of Modern Research.
The importance of the Essential Oil Industry
to the British Empire.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, MARCH 20. People's League of Health, at the
ROYAL SOCIETY OF ARTS, John Street, Adelphi,
W.C., 6 p.m. Sir Frederick Mott, "Mind
and Body."
Geographical Society, 135, New Bond Street,
W., 8.30 p.m. Mr. H. Temperley, "The
Geography of the Treaty of Rapallo."
Mechanical Engineers, Institution of, Storey's
Gate, S.W., 7 p.m. (Graduates' Meeting.)
Captain H. Whittaker, "Hydro-Electric Course
at the University of Grenoble."
Victoria Institute, Central Hall, Westminster
S.W., 4.30 p.m. Rev. R. F. Horton, "Sunday
Observance."
British Architects, Royal Institute of, 9, Conduit
Street, W., 8 p.m. Mr. H. D. Searles-Wood,
"The Building Timbers of the Empire."
University of London, at the Royal Society of
Medicine, 1, Wimpole Street, W., 5 p.m.
Prof. H. Roger "Les Fonctions du Poumon."
At King's College, Strand, W.C., 5 p.m. Mr.
E. Bevan, "Dogma."
Automobile Engineers, Institution of, Glasgow,
7.30 p.m. Mr. A. A. Remington, "The Design
and Function of Laminated Automobile
Suspension Springs."
Electrical Engineers, Institution of (Sub-Centre),
The University of Liverpool, 7 p.m. Messrs.
L. J. Romero and J. B. Palmer, "The Inter-
connection of A.C. Power Stations."

TUESDAY, MARCH 21. Statistical Society, at the ROYAL
SOCIETY OF ARTS, John Street, Adelphi, W.C.,
5.15 p.m. Mr. J. Y. Hart, "Sickness Data of
Elementary School Teachers in London, 1904-
19."
Civil Engineers, Institution of, Great George
Street, S.W., 8 p.m.
Photographic Society, 35, Russell Square, W.C.,
7 p.m. Mr. S. Bridgen, "Landscape from
the Practical Side."
Marine Engineers, Institute of, 85, The Minories,
E., 8.30 p.m. Captain A. Carpenter, "The
Depths of the Sea."
Automobile Engineers, Institution of, Coventry,
7.30 p.m. Mr. A. A. Remington, "The
Design and Function of Laminated Automobile
Suspension Springs."
Electrical Engineers, Institution of (N. Western
Centre), 17, Albert Square, Manchester, 7 p.m.
Mr. J. Frith, "Specifications and Estimates."
Anglo-French Society, Scala House, Tottenham
Street, W., 6.15 p.m. M. M. Thierry, "Le
Theatre de Paul Herveau."

Royal Institution, Albemarle Street, W., 3 p.m.
Sir Arthur Keith, "Anthropology of the
British Empire." (Lecture V.)
Zoological Society of London, Regent's Park, W.,
5.30 p.m. (1) Mr. Gilbert Blane, "Notes on
the Zebras and some Antelopes of Angola." (2)
Mr. R. I. Pocock, "On the External Characters
of some Histiocomorph Rodents." (3) Mr. H.
R. Hogg, "Some Spiders from South Annam."

WEDNESDAY, MARCH 22. University of London, King's
College, Strand, W.C., 5.15 p.m. Prof. Nils
Bohr, "The Quantum Theory of Radiation
and the Constitution of the Atom." (Lecture
II.)
Geographical Society, Burlington House, Picca-
dilly, W., 5.30 p.m.
Aeronautical Engineers, Institution of, at the
De Havilland Aircraft Works, Stag Lane,

No. 3.618

VOL. LXX.

FRIDAY, MARCH 24, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MARCH 27TH, at 8 p.m. (Cantor Lecture.) GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, "The Constituents of Essential Oils." (Lecture II.)

WEDNESDAY, MARCH 29th, at 8 p.m. (Ordinary Meeting.) SIR THOMAS OLIVER, M.D., LL.D., D.Sc., F.R.C.P., "Alcohol in relation to Industrial Hygiene." (Shaw Lecture.) SIR ROBERT ARMSTRONG-JONES, C.B.E., M.D., F.R.C.P., in the Chair.

SIXTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 15th, 1922; SIR ROBERT MOLESWORTH KINDERSLEY, C.B.E., in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Roberts, Alfred Edwin Priestland, Birmingham.

Vardy, William Andrew Shakespeare, Normanston.

The following candidates were balloted for and duly elected Fellows of the Society:—

Donald, Bernard Speirs, London.

Seago, Miss Muriel, Harrogate.

A paper on "Certain Aspects of the Problem of Exchange Stabilisation" was read by Mr. Oswald Toynbee Falk, C.B.E.

The paper and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURE.

On MONDAY, MARCH 20th, MR. GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, delivered the first lecture of his course on "The Constituents of Essential Oils."

The lectures will be published in the *Journal* during the Summer recess.

PROCEEDINGS OF THE SOCIETY.

THIRTEENTH ORDINARY MEETING

WEDNESDAY, FEBRUARY 22ND, 1922.

SIR HERBERT JACKSON, K.B.E., F.R.S., Vice-President of the Society, in the chair.

THE CHAIRMAN, in introducing Dr. Alexander Scott, the author of the paper to be read that evening, said that the Department of Industrial and Scientific Research had recently instituted a scheme for a systematic investigation of the application of science to the preservation and restoration of museum specimens. That was a very extensive undertaking, because museum specimens included practically every material that was known. The Department had thereby performed a notable service to the public; the magnitude of that service might perhaps not be understood for some generations, but that it would be of the greatest value in the present and in the future there could be little doubt. The best scheme of research might have very little chance of success unless the right man could be found to foster and direct it, and the Department had been singularly fortunate in that Dr. Scott had been willing to place at its disposal his exceptional knowledge and wide outlook over the whole domain of science, in order to direct the scheme. Dr. Scott would describe in his paper the great progress that had been already made.

The Paper read was:—

THE RESTORATION AND PRESERVATION OF OBJECTS AT THE BRITISH MUSEUM.

By ALEXANDER SCOTT, Sc.D., D.Sc., M.A., F.R.S.

Before proceeding to consider the subject proper of this paper some points which may be raised in what follows may be made clear by giving a simple definition of a Museum from our present standpoint. A museum is a collection of objects, natural and artificial, brought together into one building from the ends of the earth and removed

from the places where they were produced and stored under conditions usually totally unlike those for which they were individually fashioned. They consist of materials of every conceivable variety, stone or wood, which may be hard, soft or porous, metals which vary in their qualities of softness, hardness and resistance to external influence, clay, baked or unbaked, glazed or unglazed, and so on. It is not only that these objects have been removed from positions and conditions for which they had been especially designed, but that in the ages which have elapsed since they were fashioned, a great majority have passed through a series of situations and changes of conditions which have profoundly modified them, sometimes adding to their beauty, but too often tending to their deterioration and final destruction.

To discuss the methods of preventing, or, at least, completely arresting these latter processes is our present object. We must start with two simple axioms; there is a cause for every change and there ought to be a cure for it.

To get at the cause we must endeavour to arrive at the history of each object and find out what have been the most potent of the agents producing these changes, then we can follow up this knowledge, by removing these active substances or of neutralising their action by some kind of antidote. In the thousands of years which have elapsed since man began to make these specimens now stored in the museums of the world, many upheavals of infinite variety—social, political, volcanic, etc.—have taken place. One common result has been that the objects have become buried in the soil at greater or less depths. This, in many cases, has tended towards their preservation, whilst, on the other hand, it has also tended to change many more, mostly for the worse. Ordinary soil contains many agents in relatively small quantity, but which working for hundreds of years bring about wonderful chemical changes. These changes are often aggravated by the removal from a damp or moist soil, of objects, whether of metal or of stone, into a dry atmosphere. The most active of these substances are the chlorides, nitrates and sulphates of sodium, ammonium and calcium.

Had all objects been thoroughly washed and cleaned when acquired and before being placed in cases for study and exhibition, most museums would have been

incomparably richer in the possession of precious objects as well as in their being in infinitely better condition. This is well known to all curators of museums, but the infinity of varieties of what we may well call the diseases, as well as the number of places where they have broken out, have until recently prevented a systematic and scientific attack on the many problems which have arisen.

As the great majority of these manifestations of tendency to deteriorate are due to chemical action of a more or less complex nature, the natural procedure is to establish a chemical laboratory where the causes and effects of the various agents at work may be carefully investigated. This has been recognised abroad for many years, as in Berlin, Stockholm and Copenhagen. In Berlin especially an elaborate and carefully designed laboratory for purely museum work has been at work for over twenty-five years. It speaks volumes for the energy of the Director and the staff of the British Museum that such magnificent work on a collection of unparalleled extent and variety has been done without a corresponding adjunct. It can only have been done by wasting the time of the Heads and staffs in each department in getting up details of methods and testing of remedial reagents when such assistance and information could have been given at once by members of a scientific staff. It is as unfair to the Head of a department who has found some of his valued possessions with a malignant disease to perform a crucial operation as it would be to expect the headmaster of a boarding school, having found one of his pupils suffering from appendicitis, to try to remove that boy's appendix in the hope of achieving a complete cure.

A time came, however, owing largely to the war and to the varying atmospheric conditions to which the objects had to be exposed in consequence, when organised scientific assistance became necessary, and in 1920 a small room, which could be used as a chemical laboratory was set apart where the solution of many of the problems could be attempted. It is with what has been done in that room and in this short space of time that we are to deal now.

For many reasons, historical as well as others, it is natural and convenient to begin with objects of stone, as this is the substance ready at hand for the earliest

artificers, and it occurs in an infinite variety of degrees of hardness, porosity and colour. All ordinary rocks are porous to a certain extent, even if we include such a hard substance as agate. The more porous a stone is, the more liable is it to decay, because it is thus able to absorb and retain substances of a destructive nature. Every one knows the disruptive power of water when passing from the liquid condition of water to the solid and crystalline condition of ice. The same effect is produced even if the cause be not identical, when any substance crystallises from its solution, and if this solution is permeating the pores of a solid, such as sandstone, limestone or other rock, and there crystallises, the particles of the rock, especially on the surface, are forced asunder, and a shower of rain washes them away. The soluble and crystallisable material, unless removed, alternates between becoming a solution and becoming crystalline with every period of moist atmospheric conditions, and dry ones, so that a relatively small quantity of such a soluble salt may rapidly lead to the total destruction of a hard stone specimen. The great danger is in this *alternation* of dry and moist conditions, just as in the case of the water pipe which is liable to no change, if kept permanently frozen, or if never allowed to freeze. Just as you may protect your water pipe, as such, by having no water in it, so the specimen may be protected indefinitely by having in it no material which can attract and lose water alternately. The cause of the deterioration is the soluble material, and the cure is the total removal of that soluble material, preferably by washing and soaking first in ordinary water, and then in distilled water. In some cases, the salts in the pores of the stone may be caused to become insoluble, and thus innocuous, but this process often introduces another soluble salt, so that, if prolonged washing can remove the soluble material without injuring the specimen, this is by far the safest and best procedure to adopt for the preservation of the object.

[Here are slides showing an ancient Egyptian vessel of white limestone, with its incrustation of crystalline material, and after the removal of the crust. The fractures produced are clearly shown.]

The porosity of hard stone enables it to store up moisture, and the moisture to extract from the felspar of granite some

potash salts, with which to aid the growth of lichens, as the following slides show. This pale grey lichen adhered so firmly to the hard granite rock that attempts to remove the lichen by mechanical means threatened at the same time to remove the pigment. By means of dilute ammonia the lichen was rendered soft and almost gelatinous, whilst the pigment was unattacked, so that gentle rubbing was all that was required to remove the lichen, and to leave the painting unimpaired.

Unfortunately, it is not only paintings on hard rock that suffer from vegetable growths of one kind and another. Especially liable to such growths are water colour drawings, those with chalk and pencil, and even those produced by printer's ink, such as engravings and etchings. There seems to be but little doubt that the cause is due chiefly to the germination and growth of moulds and their spores, these spores occurring in the paper on which the pictures are made. They grow and feed upon—not the cellulose of which the paper is made, but almost entirely on the substances used as size to bind the fibres together and give the paper strength and consistency. These spores and the various bacteria and similar organisms endowed with life, may come from the water used in the manufacture of the paper, but much more probably from the materials, gelatinous and albuminous, of which most sizing materials consist. Given a moist atmosphere, with a suitable temperature, the spores and bacteria have all that is required to enable them to feed on and destroy the size in the pores of the paper. This is easily proved by taking two sheets of the same sample of drawing paper and keeping one in a very dry atmosphere, whilst the other is taken to the seaside for a month or so. If both are now compared by floating on pure water, the sheet which had been at the seaside shows clear wet patches, whilst the other retains its opacity. These clear patches are where the size has been destroyed by growths, and where water now easily penetrates the cellulose fibres. Papers vary considerably in their tendency to show mildew spots due, in great measure, to the more or less drastic bleaching of the paper pulp, the care in the preparation of the size, and the temperature to which the paper has been exposed before finishing. The spots produced are only too often of a brown colour, due

to the substances produced by the organisms. We are in quest of a safe and sure agent which we can depend upon to destroy all such forms of life, without destroying either the paper or the pictures upon the paper. When the picture is in black and white, as in an engraving or etching in which the black pigment is carbon in some form retained on the paper by an oily medium, such as printer's ink, it is comparatively easy to destroy both the coloured products and the forms of life which gave rise to them by means of oxidising and bleaching agents. Personally, I prefer common bleaching powder in dilute solution, in conjunction with dilute hydrochloric acid for this purpose. I have many prints, treated more than thirty years ago, which have shown no tendency to become spotted again in any way, nor has the paper in any way deteriorated. Other reagents which may be used are various *per*-salts, such as ammonium, sodium and potassium *per*-sulphates, and hydrogen peroxide.

The solution of hydrogen peroxide as it occurs in commerce is liable to contain sulphuric, phosphoric and hydrochloric acids, as well as salts of barium and other impurities, which are objectionable.

Although the question of the fading of water colours is outside our subject, one commonly employed white pigment, which is liable to change and become black, deserves mention in this connection. This is white lead, which is known to artists under various names, such as "flake white," "ceruse," etc. and chemically as basic lead carbonate. The atmosphere of cities is especially liable to contain small quantities of sulphuretted hydrogen, and this meeting the white lead changes it into black sulphide of lead, thus destroying the purity and appearance of the picture. If we can change the black sulphide of lead into white sulphate of lead, we should be able to restore the picture to its original brilliance. It has long been known that hydrogen peroxide was able to effect this chemical change, but it was, to say the least, rather a risky operation to apply even a purified solution of hydrogen peroxide to the picture. The operation can be carried out with perfect safety by employing, not the solution, but the vapour from a hydrogen peroxide solution in the following way. Prepare a thin slab or block of stucco by casting plaster of Paris in a suitable mould, and after drying the slab thoroughly, distribute over it immediately

before use a solution of hydrogen peroxide. Over this block, which must not be at all wet, expose the print to be bleached, keeping it just off the block ($\frac{1}{8}$ to $\frac{1}{4}$ of an inch) by one or two threads and leave it for a few hours, or over night, when the black sulphide will usually have entirely disappeared if the medium employed with the flake white had been water, or dilute gum. If resins have also been employed it may require days to restore perfect whiteness. The "foxy" marks so common may also be removed by a prolonged exposure to the vapour.

[Slides to illustrate these actions were here shown.]

Leaving the subject of pictures on paper to those on metals, which might be expected to be much more permanent, we find that here also we have many causes at work which tend to destroy even these. The colouring matters employed in enamels are really varieties of glass coloured by small quantities of the metals themselves or their oxides, silicates, borates, etc. The design is formed by the application of the various coloured glasses in fine powder. When all are arranged the metal and the glass powder are raised to such a temperature that the glass is fused and adheres more or less firmly to the metal. After the fusion is complete the enamel is allowed to cool slowly in either an oxidising or a reducing atmosphere, depending on the nature of the enamels employed. Most metals expand more than materials such as glass: therefore, if an artistic enamel is subjected to changes of temperature, each change produces a corresponding strain between the metal and the various coloured glasses fused upon it. This may be lessened and the strain relieved to a large extent by making the metal very thin, or it may be possible to add certain ingredients to the glasses so as to make them more elastic and accommodating. In time, however, if any large enamel be examined it will be found to exhibit cracks in its own substance, and if on a tarnishable metal, such as silver, discolouration may be traced only too easily from these cracks under the enamel, indicating that the metal and the glass have parted company, and that the air has penetrated this space. Unless one is prepared to take the dangerous and drastic step of trying to remelt the glassy material on the metal, all that can be done is to arrest the further deterioration. This is best

done by means of a suitable varnish applied after all the air possible has been extracted from the crevices between the glass and metal by means of a good air pump, and then before allowing any air to enter to flood the enamel with the varnish. For many reasons a ten per cent. solution of dried Canada balsam in good benzol (not benzoline) was used apparently with perfect success. If the enamel be lifted out of the bath of varnish and simply drained and allowed to dry we may regard the operation as finished, the solution which has penetrated the recesses between the metal and the glass retaining the enamel in its place and preventing it from becoming detached and being lost. The coating of varnish remaining on the outside has also an important function to perform, for it is well known that many portions of enamels and many kinds of glass tend to "sweat" in damp weather. This is due to excess of alkali used to increase the fusibility of the enamel or to other substances to increase the desired effect, whilst incurring the risk of adding undesirable properties. The varnish also adds brilliance and transparency to those parts of the enamel which have become dimmed as a result of the "sweating" and the formation of tiny crystals known as devitrification.

From enamels it is natural to proceed to the consideration of metals themselves, their tarnishing, corrosion and decay. In these respects we have an infinite variety stretching from gold, which may be said to be absolutely unalterable under ordinary conditions, to metals, such as magnesium, calcium and sodium, the last named tarnishing in an ordinary atmosphere as soon as a clean surface of it is exposed. The ordinary metals, which occur and are used for small objects, may be arranged in the following order as regards their permanence under ordinary climatic conditions:—gold, silver, copper, lead, zinc, iron. In addition to the metals themselves, we may have their mixtures or alloys, which may also contain in addition to the above, tin, antimony and arsenic, to mention only three of the most common. Each alloy has its own characteristic stability and corresponding liability to change. Here then, is an inexhaustible field for changes of all kinds and also for research as to what is the best metal or alloy to withstand any given set of conditions.

Pure gold, as already stated, may be said to be quite permanent but as soon as

it is alloyed with any of the metals in the foregoing list, possibilities of change arise and the power of resisting change diminishes as the quantities of the added metal increase.

Pure silver, on the other hand, although not readily attacked by a pure atmosphere, is by no means able to withstand the action of common salt in solution, especially if air be present. If the silver be alloyed with copper or with lead, the alloy is attacked with greater readiness, the baser metal being attacked whilst the silver may be left in a more or less coherent and spongy form through the mass of compound formed from the other metals which have lost all semblance of metallic properties.

A search for remedies for the various forms of decay leads to a fairly simple explanation and also correlation of the chief chemical reactions which take place and are the causes of this corrosion. The final agent may be said to be the oxygen of the air, although when dry and pure it would have little or no effect. It is aided by what, if we desire to be fashionable we would call "catalysts," agents which aid and abet the real agents, although in themselves insignificant in amount. Of these, moisture, either as water or as steam, carbonic acid gas and common salt are by far the most important and the most effective in aiding the oxygen in its work of destruction. All three occur in our atmosphere, in our water supplies and in our soils.

The chemical actions are in reality very simple. If we place some pure common salt in a pure silver dish with a little distilled water and leave it over night, we find that the silver has been attacked and a certain amount has entered into solution in the brine. This can be proved by pouring the brine into a larger quantity of water, when an opalescence is produced and can be rendered more apparent by the addition of a few drops of potassium iodide solution. If, however, instead of pure silver an alloy of silver and copper be subjected to the action of moist common salt, we may assume that both metals are attacked, but any silver chloride which may be produced is reduced to metallic silver again as long as any metallic copper remains in the alloy, the silver being brought back from its chloride in a spongy or other more or less coherent form. The action of the air and small quantities of common salt continues until the whole of the copper is converted into a porous brittle mass of oxides, car-

bonates and oxychlorides of copper through which the silver is distributed.

It must not be imagined that this type of action proceeds only in moist soils. Very many objects in museums are thickly incrustated with these chlorides of copper and of iron, and these incrustations, with the assistance of the moisture ever present in our atmosphere, go on quietly with their destructive work, for which they possess all the agents necessary. It is not uncommon to class especially the copper compounds as "malignant" and harmless, and it is often apparent to which class any example belongs by simple inspection by an experienced eye.

The destruction of iron is much more rapid and much more difficult to arrest than in the cases of copper and silver and other alloys.

A word of warning ought to be given with regard to a commonly accepted method of treating iron objects more or less thickly coated with rust.

After washing in two or three changes of water, the specimens are dried and then immersed in a bath of melted paraffin wax at a temperature above the boiling point of water. The hydrated oxide of iron (or rust) is rarely, if ever, heated to such a temperature as to remove all the *chemically combined* water, so the coating of paraffin wax seals it in and in time it and any chlorine still remaining in the coating continue to attack any metallic iron present. The compounds so formed increase so much in volume that the skin of paraffin wax is ruptured and atmospheric air admitted when the corrosion once more proceeds apace.

The real demon is common salt, and its deadly sting is the chlorine which it contains and gives up to the metal. Therefore, if it is desired to preserve any metallic object whatever, it must be regarded as essential to remove from it every trace of chlorine either by chemical, electrical or by some other method applicable to each individual case.

A certain amount of chlorine may be removed by simple washing, but unless we can convert the chlorine in the usually insoluble oxychlorides into a soluble form such as sodium or ammonium chloride, there is but little prospect of success. The objects should, therefore, be boiled with caustic soda solution or with a solution of sodium carbonate or in many cases sodium sesquicarbonate, followed by copious washing as

long as the wash waters indicate the presence of chlorine when tested with silver nitrate and dilute nitric acid. Finally, the last traces of chlorine should be urged to leave the metallic object by the application of a weak electric current, so arranged that the specimen is the negative pole and the positive pole a plate of zinc, copper or silver, and the liquid electrolyte either very dilute sulphuric (or other) acid or a weak solution of soda or other alkali.

By careful manipulation it may be possible to remove the chlorine without destroying or injuring the "patina" to any great extent, and it may be possible to restore or produce a patina by such means which will rival that which so far has only been produced by slow action going on for centuries.

In the case of coins and their cleaning and restoration by means of ammonia and acid reagents, it must ever be borne in mind that these reagents in presence of air and oxygen are corrosive agents, that is, they attack not only the impurities on the metal, which are still there, but they attack the metal itself, even in the case of silver. To employ such solutions with safety, there ought to be present also some substance known chemically as a "reducing agent," such as sodium sulphite, stannous chloride and formic acid. The last named of these, formic acid, employed in various strengths seems ideal for cleaning silver objects, especially when used warm. This is due to the fact that silver formate cannot exist at temperatures much above the ordinary, but if formed is destroyed by gentle heat into silver and carbonic acid.

Lead is in many ways one of the most durable and resistant of metals to many powerful chemical reagents. On the other hand it has an "Achilles heel" through which it can be attacked and corroded very rapidly by many reagents usually considered weak. Organic acids, such as acetic acid or vinegar and many fatty substances, behave towards it much as the chlorine of common salt does towards copper and iron. The lead objects contaminated with traces of these substances in presence of air, moisture and carbonic acid rapidly become brittle and more or less shapeless masses of basic lead carbonate (white lead).

The objects so far dealt with, with the exception of pictures on paper, have been what are usually termed inorganic. Besides

stone and rocks early man had another type of material with which to work and which he did employ very largely. In the trees which he saw growing around him he had a large choice of material, much of it in a form in which it was available for immediate use or required but little to be done to adapt it to his varied needs. From its nature it was not to be expected that it would endure as objects of stone or metal. This in itself is enough to warrant our treasuring specimens which have come to us in safety through the ages. One very interesting case which has been successfully dealt with and decay arrested is a set of figures which were presented to the Museum 50 years ago. They were buried under 14 to 16 feet of guano on the Macabi Islands, and as according to Alexander von Humboldt the guano deposit only amounts to a few lines (let it be an inch) in 300 years, we can see that these can boast of no mean antiquity. Their threatened destruction was due to the action of various salts of ammonia combined with the alternation of moisture and dryness of the atmosphere.

Much of what was said about the causes of decay and the preservation of paper applies also to wood. In addition to the destructive agencies of microscopic size are those of beetles and other wood boring insects, the destruction of which calls for other and more strenuous types of poisons which can be relied on to destroy them, and, what is still more difficult to secure, the destruction of their eggs. The destruction of many precious objects of wood and of pictures painted on wood panels, is often far advanced before it is detected. It is to be hoped that in the new laboratory being constructed at the Museum, these and many of the pressing problems requiring solution will be successfully solved.

DISCUSSION.

THE CHAIRMAN (Sir Herbert Jackson), in opening the discussion, said that the subject of which the author had undertaken the direction was an exceptionally fascinating one. As the author had described it, it sounded very simple, but in reality it called for a very wide outlook on science, not only in chemistry but also in physics and in the biological sciences, and in addition it required a very large amount of common sense and that particular quality which was not easily obtained by training, namely, special sympathy with the subject and a real desire to do the best possible to

preserve the very valuable relics contained in museums. Scientific men were singularly modest and looked for very little reward for their labours, but he thought the time would come when the author's name would be blessed by future generations, who, if it were not for the work of the author, would in many cases only be able to read descriptions of the various objects instead of seeing them. The work seemed very simple, but it should be remembered that if a mistake were made it might lead to the destruction of a valuable article. The author said in his paper that this, that and the other were tried, but, if one thought of the recondite science that had to be employed in order to obtain the results he had achieved, one realised how useless research of the kind would be in the hands of a man who had not wide experience and catholic tastes in science.

SIR SIDNEY HARMER, K.B.E., Sc D., F.R.S. (Director of the Natural History Departments of the British Museum), said he was sure everyone present would agree that the British Museum at Bloomsbury was extremely fortunate in having secured the author's assistance in working out some of the problems discussed in the paper. Those who had been concerned with museums had been aware for a long time of the existence of many difficulties, some of which the author had described, and they had been trying, perhaps in a rather crude way, to find solutions to those difficulties, generally being conscious of the fact that they were themselves insufficiently equipped with regard to their knowledge of chemistry. There was no doubt that, as the author had said in his paper, a great many of those problems were simply and solely chemical. Dealing with the question as it affected the branch of the British Museum at South Kensington, the material there was in the main of an organic nature, whereas the author had been dealing to a large extent with inorganic substances; but to a certain degree the problems at South Kensington were very much the same as those which the author had described. For instance, in connection with the preservation of metals, very much the same kind of difficulties had been experienced at South Kensington as at the Museum at Bloomsbury, great trouble having occurred owing to the alteration of masses of meteoric iron. It had been necessary to find a remedy for that, and there was now an effective method of treating those meteorites so that deterioration by rust was prevented. Another point which had struck him in the paper was the author's reference to the cracking of enamel. Curiously enough, exactly the same difficulty had been experienced at South Kensington with regard to the enamel of teeth. Nothing was more common, when fossilised teeth were dug up out of the ground than to find that after they had been kept for a certain time the enamel began to chip off in exactly

the same way as did the enamel coatings of metal surfaces described by the author, and the treatment adopted was fundamentally the same. With regard to the question of carbon bisulphide, he thought entomologists might be able to give the author some useful information on that subject. He believed it was well known to entomologists that carbon bisulphide was an extraordinarily effective substance in destroying insects in all stages of their existence, and prussic acid was known to have similar effects. A few years ago he happened to be in Stockholm, and there he saw one of the most beautiful pieces of museum apparatus he had ever seen. It was a large apparatus for treating objects with carbon bisulphide, being in the form of a large horizontal cylinder with a diameter of 9 ft. The museum to which the apparatus belonged was one concerned with the exhibition of furniture, textiles, and similar things, and it was the practice at the museum to pass through that chamber every single object that came to the museum. The process was very much the same as that which the author had described. The air was first exhausted, so that it was all removed from the finest cracks of the object, and when that had been done the carbon bisulphide vapour was admitted to the cylinder. A single operation was effective in practically all cases. He thought that the problems involved in dealing with organic material were of a more complicated nature than those which the author had described. The paper dealt with comparatively simple chemical questions, but, when one was dealing with organic materials as the substances being acted on and with a further organic process concerned in their deterioration, the problem became a much more complicated one. He might allude especially to the alterations caused by the action of moulds and bacteria, which were sometimes very difficult to understand. He had in mind a case which had been submitted to the Museum a few days ago of some hose, used in connection with fire engines, which was subject to a mysterious disease resulting in the deterioration of the material of which the hose was composed. Similar cases had been submitted previously, and very great difficulty had been experienced in ascertaining the cause of the disease. Up to the present the cause in the case of the hose had not been ascertained, but it was very possibly connected with bacterial action. There was one case he would like to mention in the hope that the author might be able to give some assistance in regard to it; it was very similar to some of the cases described in the paper. The marine shells in an ordinary conchological cabinet, especially the more highly polished shells, such as cowries, were attacked by a disease which caused a thick layer of white efflorescence to appear on the surface, which entirely concealed the shape of the shell. When it was washed off one found that the process had been going on for some time and the whole of the substance

of the shell had deteriorated. It was extremely difficult to find a cure for that disease. Various attempts had been made to do so but no one had really achieved any permanent success. The disease only attacked certain shells in a cabinet. In the latest investigation of which he had heard the conclusion was arrived at that butyric acid was in some way connected with the disease, and it was supposed that it was brought about in the first instance by the presence of organic matter in some of the coils of the shell. It was extremely difficult to remove all the organic matter from the shell, and the theory put forward was that the soft tissues left set up various changes which resulted in chemical processes, which in the course of time acted on the shell. The author seemed to think that paper which was composed of pure cellulose would not under any circumstances suffer from diseases caused by bacteria and similar organisms. Without wishing to dispute that, he might mention that there was a good deal of evidence to show that pure cellulose, or at any rate the derivatives of cellulose, could be much more nutritious to certain organisms than the author implied. If one examined the conditions under which furniture beetles devoured wood, it was found that the larvæ of those beetles seemed to subsist exclusively on the wood-fibre itself, which, judging from their plump appearance, they must find highly nutritious.

SIR FRANK HEATH, K.C.B., (Secretary to the Department of Scientific and Industrial Research) said he agreed that those present were deeply indebted to the author for his paper, because, apart altogether from those who were professionally interested as representing museums, most people were to some extent collectors themselves. He thought every dealer in artistic and archaeological objects in London ought to have come to the meeting, and he was certain that on some future occasion when the author gave another paper those dealers would attend. The Chairman had said that the Department of Scientific and Industrial Research was to be congratulated on having secured the author's services and gave some indication of the reasons for that, and personally he thought that there was in the author a combination of qualities which it would have been extraordinarily difficult to find anywhere else. Dr. Scott was not only a scientist of very wide knowledge and experience but he was also a collector and an artist and knew the artistic value of the objects with which he was dealing, which was an essential factor in carrying out research where one could not afford to make a mistake. The hopeful point about the experiment—it was very little more than an experiment at the present time—was that, in dealing with a great variety of problems in none of which he could afford to make a mistake, the author had succeeded in finding a solution in a very large proportion of the cases.

That showed how hopeful the attempt was to attack the subject of the restoration and preservation of museum objects in a really systematic way. The Department of Scientific and Industrial Research would have been quite unable to undertake the experiment if it had not been for a combination of accidents, one of which was, as the author had mentioned, the breakdown of museum equipment during the war. The British Museum lost more than one of the men upon whom it had relied for the kind of restoration work described in the paper, and moreover the conditions under which the objects were stored were very much worse during the war than before that time. Soon after the war was over, Sir Frederic Kenyon told him of the difficulties he was experiencing and asked him if the Department could do anything in the matter. After certain enquiries had been made and advice obtained from scientists in the Department, it was suggested to Sir Frederic Kenyon that perhaps Dr. Scott might be induced to go to the British Museum so that Sir Frederic might consult him on the subject, and the result of that was an agreement between the British Museum and the Department of Scientific and Industrial Research to begin an experiment on a co-operative basis. The Museum provided the accommodation and the Department undertook the maintenance of the laboratory. The accommodation at the present time was, as the author had said, very limited, but in the near future it would be much more commodious and more suitable for the extension of the work. Sir Francis Ogilvie had just reminded him how true was the Chairman's remark about the unselfishness of men of science when dealing with problems in which they were interested. At the beginning of the experiment the author gave his services freely, and personally, as an official of the Department, he was ashamed to think how modest was the fee that the author now accepted from the Department. It was not a fee that in any way represented the accumulation of knowledge, the time, the ingenuity and the scientific experience which the author was devoting to the work. What were the lessons that the paper brought out most clearly? He thought the first lesson was that if this country was to continue the collection of valuable and often unique specimens, whether of artistic value or of purely scientific and historical value, such as those in the Natural History Museum at South Kensington, it literally could not afford to store those objects without some special scientific control of the conditions under which they were stored. The second lesson, for which there was ample evidence in the comparatively narrow field that had been attacked up to the present, was that before any object went into a museum at all it ought to pass under a systematic review in a properly equipped laboratory. From a financial point of view it would be found well worth while to do that, but before that could be

done it was necessary to convince not only the directors of museums, who were as a class intensely sympathetic, but also a rather hard stressed country that it was worth while. He did not know what the fate of the Department of Scientific and Industrial Research would be under "the great axe," but if it was left with the power to do so it was prepared to go on with the experiment which was under discussion that evening. That experiment had been centred at the British Museum, partly because the British Museum first discovered the need but especially because there were statutory obligations laid upon the British Museum which prevented any object being removed from its precincts, and therefore it was necessary for the laboratory to be established within the walls of the Museum. He did not imagine, however, that that Statute prohibited objects belonging to other national museums which were under no such statutory obligations being brought into the laboratory, and if other national museums cared to ask for the assistance of the Department he was sure the Department would be quite willing to give that assistance. He did not think the Trustees of the British Museum would be reluctant to give their consent to such an extension of the work. The author had already described how he had been able to give assistance to the National Portrait Gallery. With reference to the remarks that had been made by Sir Sidney Harmer, he thought the Department might be able to help Sir Sidney in connection with the attack of bacteria upon cellulosic and other organic substances. Some extremely important and interesting bacteriological work was done by an officer under the Admiralty during the war at Hopton Heath. That work proved of such interest that the Department of Scientific and Industrial Research had arranged a complete interchange of information between the work of that particular investigator and the Cotton Research Association, which was one of the largest of the Research Associations connected with the Department. Since the war the Department had arranged with the Admiralty to retain that particular officer in order to work upon the problem of bacteriological attack on cellulosic materials of various kinds, not with the object of finding a means of preserving those materials, but with the exactly opposite object of finding out how cellulosic materials could be broken down in the sort of way that Sir Sidney Harmer had said was such a trouble to him. If an exchange of experience could be arranged with Sir Sidney, it might be found that the organisms which were so troublesome to him were the very things that were being looked for in another connection. He never dealt with any of the ramifications of his Department without finding that they led to relations with and effects upon problems and difficulties quite unthought of from the point of view from which the particular difficulty was attacked.

MR. A. F. KENDRICK (Department of Textiles, Victoria and Albert Museum) said he entirely agreed that the Department of Scientific and Industrial Research had found the right man for the work in securing the services of the author, and there was another point he would like to make in connection with that. The author had stated in the paper that certain wooden figures which had been acquired by the British Museum in 1871 should have been dealt with at that time with the object of arresting decay, but, as the author would not have been there to deal with them then, perhaps it was as well that nothing had been done to them before the present time. A few years ago he met a well known chemist who was the Director of the Imperial Austrian Institute of Agricultural Chemistry, Dr. Bolle, and, in discussing the subject the author had dealt with that evening, Dr. Bolle said he had found a remedy for the beetle in the wood panels of old pictures and that he had been going through Europe visiting the Directors of the various picture galleries and had made converts everywhere he went, the Directors being unanimous that he had found the remedy. Then Dr. Bolle had to consider the question of how he was to begin dealing with the collections, and he found the Directors unanimous again—they all said that question would have to be left over for their successors to deal with! Dr. Bolle agreed with them, because he did not think that at that time, ten or twelve years ago, they were ready to begin. It was obvious that the scientists were now ready to begin, and, speaking on behalf of those interested in art, he wished to say how glad they were that at last the scientists were prepared to come and help. The question of the restoration and preservation of works of art was not a simple matter, even with the methods that had now been discovered. The forces of restoration had a way of deserting to the enemy; there were times when it was found that methods which seemed perfectly safe failed in one way or another. To give an instance of that, a few years ago in the north of England there was a tapestry which was a marvellous work of art and had a value of many thousands of pounds. That tapestry was in existence to-day, but it was in two pieces, divided right across the faces of the principal figures in it. That had happened in the following way: The family to whom the tapestry belonged realised its value and as they were going abroad for a time, they took advice as to what would be the best way of keeping it. They were told that a cylindrical metal case should be made, into which the tapestry should be put with a few naphthalene balls in case there were any eggs of moths within the tapestry. That was done, but when the tapestry was taken out later on it was found to be in two pieces. He did not know what had been the cause of it, but it seemed to be due to a kind of collusion between the naphthalene balls and the metal

case first of all to attack the metal threads in the tapestry, which were destroyed where the tapestry had been resting on the metal. He supposed such a thing would not happen to-day, certainly not if the advice of the author was taken on the subject. That was a case which showed the advantage of not having started the work of preservation and restoration too soon; if it had been undertaken fifty years ago damage would have been done that would now be irreparable. That work was a great battle, and it was a battle that would ultimately be lost, because Nature had decreed that every thing sublunary should perish; the destruction of the objects could only be delayed and not prevented. He thought it was most important that those who had to do with the preservation of works of art of all kinds should combine together and state what they wanted the scientists to do, because they did not want those works of art cleaned and restored if thereby one iota of their antique artistic value would be lost. When the subject was taken up in that way by both parties concerned, perhaps a new era would dawn.

MR. WALTER F. REID said one point that was made clear by the paper was that the Trustees of the British Museum had started a very valuable work, the cost of which was a very small premium for the insurance of the invaluable contents of the Museum. Speaking as a member of the public, he thought the Trustees would be failing in their duty if they did not obtain scientific guidance with regard to the preservation of the objects that were most valuable to the present generation and would be still more valuable to future generations. There were one or two points in the paper upon which he did not quite agree with the author. For instance, he thought the use of bleaching powder in connection with cellulose was dangerous. In the explosives industry he had had to deal with very large quantities of pure cellulose, and he found that if chlorine was brought into contact with it one could not get all the chlorine out. He strongly recommended the use of peroxide of hydrogen instead; it would do nearly everything that the chlorine did. He did not agree with the author as to the use of Canada balsam for the preservation of enamels. He once made a number of slides for a microscope and used little metal rings in mounting the subjects with Canada balsam; every one of them had corroded and the Canada balsam itself was cracked in all directions and had become dark in colour, although he used the best quality that could be obtained. It might answer quite well at the time, but its effect was not permanent, and he would hesitate to put it in between metal such as copper and the surface that was liable to scale off. With regard to the preservation of wood infested with beetles, he had used bisulphide of carbon for more than twenty years, and had found it

absolutely successful. It must be used at a time when there were no beetles' eggs in the wood, because the eggs were not decomposed or destroyed by carbon bisulphide, and it was also necessary to have the article being treated at a slightly higher temperature than the bisulphide of carbon vapour. If a piece of furniture was covered with a varnish that might be acted on by carbon bisulphide, clearly it would be spoiled if the vapour were to condense upon it. The beetles laid their eggs, generally speaking, at the end of the summer, and now was the time when the grubs did the damage. With regard to Sir Sidney Harmer's remark about cellulose being an article of food for those little grubs, that was not the case. The grubs lived, as Dr. Scott said, on the substances that cemented the cellulose fibres together. In going through museums in this and other countries, one found articles of wood that had been in a very wet condition when they were dug up; they shrank and lost their form, becoming a mere shapeless mass. Some years ago he tried experiments to prevent that, starting with some piles from the lake dwellings at Glastonbury, which, when dug up, were very spongy and soft, but the moment they dried their diameter was reduced to about one-third of the original diameter. They twisted and cracked, and when put in a dry museum they could scarcely be identified by their shape. The method he adopted was a very simple one. He put the wet material, just as it came out of the ground, into a vessel containing paraffin oil, Tea Rose petroleum being what he actually used. Petrol could be used, but it was more dangerous from the point of view of fire. After a time the water was replaced by the oil; the article was put on a grating and the water would be found under the grating and the wood was then saturated with the oil. When the saturation was complete the article was taken out and drained and placed in a vessel with melted paraffin wax. When it was cold it could be handled and had its original form and would last a very long time. He showed that method at a Science Exhibition, and a week or two afterwards he received a letter from the Berlin Museum with two sheets of German forms to fill up. He filled them up and returned them, and received another letter a month or two afterwards containing a cordial invitation to him to visit the Berlin Museum. The next time he was in Berlin he went to the Museum, and when he saw the laboratory there he felt absolutely ashamed of his own country. At that time an extremely interesting subject was being dealt with at the Berlin Museum. The Germans had found in Chaldæa, or somewhere in that region, a very large number of cuneiform tablets. There were several tons of them in great masses, a chamber having been found packed full of them. They were cemented together by sulphate of lime and carbonate of lime, and some of them were insufficiently burned, so that

if they were put into a liquid, especially an acid liquid, they went to pieces. The first thing the chemist in charge of the laboratory at the Museum did was to take some small pieces of the clay and put them into a furnace, the temperature of which he could tell by a pyrometer, and he got to within a few degrees the best temperature for burning that clay. Then he put the whole block into a furnace heated to that temperature. Personally, he only wished the British Museum had a furnace it could use for the purpose; the furnace at the Berlin Museum was a beautiful one, heated by gas and with pyrometers and everything that science could devise. When the blocks came out of the furnace they were rather friable; the sulphate of lime was dehydrated and the blocks could be separated into their constituent pieces. They were then put into dilute acid, and when the bricks came out they were quite as bright as they could have been when they were put into the lime. He thought if the British Museum had a chemist who could treat things in that way as they came to the Museum it would be an excellent advance on the present system. With regard to moisture, that could not very well be kept out of an ordinary case, but the Berlin Museum had cases which were absolutely airtight at the top and the lower part dipped into a channel filled with mineral oil. Chloride of calcium or something that absorbed the moisture in the case was put into the case and no more moisture got in, because there was sufficient oil to allow for the expansion and contraction caused by the temperature. The case looked just like an ordinary one, and the objects it contained could be seen beautifully. The subject of fossils was a most interesting one. There were many in the British Museum at South Kensington and Dr. Smith Woodford had shown him a very interesting problem. That problem had to do with some bones that were embedded in fresh water limestone, which was very much harder than the bones themselves. The bones were phosphate of lime and the fresh water limestone was nearly pure carbonate of lime. He dissolved away the carbonate of lime by a very weak acid and at the same time covered over the bones as they emerged with a varnish that protected them from any action on the part of the acid. One of the bones that emerged was the breast bone of a pelican. There was one little residue inside which he could not identify until he examined it under a magnifying glass, when he found it was the bones of the last fish that the pelican had swallowed. With regard to iron, practically all the very old iron articles that were found in the ground were destroyed. An article was dug up that might have been a sword, but outside it was simply a conglomerate of mineral particles held together by oxide of iron. The outer coating could be got off very easily by chemical means. A few weeks ago Mr. Lambert, of the Guildhall Museum, showed him a key and he

found that, after removing a mass of ferruginous concrete, the wards had a thin layer of pure copper in them; they had been cemented or welded together by means of pure copper. No artisan who had ever used brass for uniting iron would use copper; therefore, that key was probably lost or thrown away at the time when copper was used. With regard to bones, people excavated barrows or graves, which contained some of the very oldest remains of the human race, and got very few bones out as there were said to be so rotten that they could not be saved. There was not a single bone found under those conditions that could not be saved. They should be treated *in situ*; the soil and the bones should be hardened together and the bones should be separated out afterwards. That could be done with wax, but that was a rather expensive method, and a very simple way was to cement the whole ground together with silicate of soda and chloride of calcium, so that it came out like a rock with the bones in it, and then the bones could be taken out and saved.

Dr. A. SCOTT, in replying to the discussion, said that with reference to Mr. Reid's remarks about Cuneiform tablets and calcium sulphate, he had tackled that problem in the same way as Mr. Reid had described. He did not know when the British Museum would be able to obtain an apparatus such as that at Stockholm which had been mentioned by Sir Sidney Harmer. He had himself thought of a vacuum in that connection and he had thought of carbon monoxide as probably the safest of all the things that could be used and the least likely to attack mineral or other pigments, although modern coal gas might answer in many cases where there were no pigments. He would prefer that to carbon bisulphide. One reason why he had not mentioned certain processes in his paper was that they had been tried for a very short time only and further experience was necessary before they could be put forward definitely. In treating specimens it was essential to have the substances absolutely pure. For instance, in the case of the tapestry referred to by Mr. Kendrick probably the naphthalene used was impure and had a strong smell due to the impurity, and the impurity probably was just the constituent which attacked the metal. When naphthalene was pure it had not very much smell. The same remark applied to carbon bisulphide; if it was used as it was bought it would attack many pigments in a picture. He had some carbon bisulphide which he had been purifying with a very powerful reagent since 1911, and it had hardly any smell. He thought it was important to keep on the safe side, and that was why he recommended the somewhat unusual method of using the soda in the form of bicarbonate, because it attacked the articles much less than even the carbonate.

His work at the Museum was extremely pleasant and interesting, owing to the variety of the subjects to be dealt with and the assistance given to him by the Heads and their Staffs in every department. He had already learned a very great deal there and he was prepared to learn a great deal more.

THE CHAIRMAN, in proposing a vote of thanks to the author for his paper, said those present had heard an account of the beginning of what he hoped—if full encouragement and opportunities were given to the author—would become a large school of scientific people who could assist the museums in preserving their material. He hoped it would not degenerate into a method by which, when the way in which decay came about had been discovered, ingenious exploiters might manage to imitate that decay so as to deceive the connoisseurs. He was sure that everybody who had any opportunity of exercising influence in any way should do so in the direction of making people realise that it was necessary to do everything possible to utilise science for the benefit of art. He agreed with Mr. Kendrick that it was perhaps fortunate that the work described by the author had not been undertaken before; he had himself seen museum specimens treated 25 to 30 years ago and they did not exist now. Twenty years hence people might say exactly the same thing about the present time. But at no time in the history of science had the important influence of minute quantities been so fully recognised—the progressive action of minute quantities that were less than could be expressed even with many noughts and a significant figure after the decimal point.

The resolution of thanks was carried unanimously and the meeting terminated.

OBITUARY.

SIR ALEXANDER HARGREAVES BROWN, BT.—Sir Alexander Hargreaves Brown died in London on the 10th inst., at the age of 77. He was a partner in the banking and issuing house of Messrs. Brown, Shipley and Co. He sat for many years in the House of Commons—from 1868-85 as Conservative Member for Wenlock, and from 1885-1906 as Unionist Member for the Wellington Division of Shropshire. He was formerly a cornet in the 5th Dragoon Guards and was honorary Colonel of the Lancashire and Cheshire R.G.A. He was elected a member of the Society in 1871. He read a paper before the Water Supply Conference convened by the Society in 1878. On several occasions he presided at Ordinary Meetings and took part in discussions.

GENERAL NOTES.

MODERN WHALING STATISTICS.—According to Sir Sidney F. Harmer, K.B.E., Sc.D., F.R.S., in a paper read before the British Association at Edinburgh, the examination of reports by Government officials, supplemented by voluminous statistics which have been furnished by the whaling companies, at South Georgia and elsewhere, to the British Museum (Natural History), shows that there are indications of a serious diminution in the number of whales, in an industry which commenced so recently as the end of 1904. In the case of the humpback, a marked decrease in the number of individuals captured commenced after the end of the season 1911-12; while there is reason to fear that a similar decline in the numbers of blue whales commenced after the end of the season 1917-18. The study of the records of the lengths of fetuses obtained principally at South Georgia in the south, and from various localities in the north, has led to the conclusion that in each of the three species (humpback, fin whale, blue whale) principally hunted there is a period during which pairing takes place with maximum frequency. In the southern whales the periods in question appear to occur approximately from July to September, and in the northern whales approximately from January to April. If these conclusions are correct, the principal breeding periods, in each hemisphere, are in winter and early spring, when the majority of the whales have left the localities in which they are mostly hunted. Fœtal specimens of a given length are thus most numerous during periods about six months apart in the two hemispheres. The duration of pregnancy does not seem to exceed twelve months; and evidence has been obtained that in the fin whale the rate of growth in the fetus is about two feet a month, during a considerable part of the period of gestation.

NEW THREAD TWISTING MACHINE.—A new twisting machine for the textile industry has been invented by a Norwegian factory owner, according to a report by the United States Consul-General at Christiania. The main principle of the new invention, in contrast to older types, is that the bobbins rotate simultaneously with the spools receiving the spun thread, causing the twisting of both ends (said never to have been accomplished before), which gives greater firmness and strength to the thread. It is claimed that this machine twists seven times as fast as older machines.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 p.m. (unless otherwise announced):—

MARCH 29.—SIR THOMAS OLIVER, LL.D., D.Sc., M.D., F.R.C.P., "Alcohol in Relation

to Industrial Hygiene." (Shaw Lecture.) SIR ROBERT ARMSTRONG-JONES, C.B.E., M.D., F.R.C.P., in the chair.

APRIL 5.—PROFESSOR ERNEST R. MATTHEWS, "Coast Erosion and its Prevention." LORD HEADLEY, M.Inst.C.E.I., in the chair.

APRIL 26.—JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry." SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the chair.

MAY 10.—MAJOR PERCY A. MACMAHON, R.A., LL.D., ScD., F.R.S., "The Design of Repeating Patterns for Decorative Work." SIR CHARLES CARRICK ALLOM in the Chair.

MAY 17.—OSWALD M. SHEPARD, "Recent Developments in Rubber Manufacture, with special reference to Rubber Machinery and the Manufacture of Tyres."

MAY 24.—GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

MAY 31. (at 4.30 p.m.)—LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock:—

APRIL 28.—F. G. ROYAL-DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the chair.

MAY 26.—PROFESSOR SIR THOMAS W. ARNOLD, C.I.E., Litt.D., M.A., Hon. Fellow, Magdalene College, Cambridge. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced:—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION.

TUESDAY, APRIL 4, at 4.30 p.m.—LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, G.B.E., K.C.M.G., "New Zealand." COL. HON. SIR JAMES ALLEN, K.C.B., High Commissioner for New Zealand, in the chair.

FRIDAY, JUNE 9, at 4.30 p.m.—MAJOR SIR HUMPHREY LEGGETT, D.S.Q., R.E., "Tanganyika Territory (formerly German East Africa)."

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETING.)

Friday afternoon, at 4.30 o'clock:—

MAY 5—PROFESSOR WILLIAM HENRY ECCLES, D.Sc. (London), F.R.S., "Imperial Wireless Communication."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester. "The Constituents of Essential Oils." Three Lectures. March 20, 27, April 3.

Syllabus.

LECTURE II.—MARCH 27.—The Classification of the Constituents of Essential Oils. The Cyclic and Olefinic Terpenes and their more important derivatives.

LECTURE III.—APRIL 3.—The Derivatives of Benzene. Alcohols. Acids and Esters. Aldehydes. Phenols and their derivatives. Heterogeneous Compounds. The Trend of Modern Research. The importance of the Essential Oil Industry to the British Empire.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, MARCH 27. People's League of Health, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m. Dr. Tregold, "Mental Deficiency."

University of London, at the Royal Society of Medicine, 1, Wimpole Street, W., 5 p.m. Prof. P. Duval, "Données actuelles de la Chirurgie Intra-Thoracique." At King's College, Strand, W.C., 5 p.m. Mr. E. Bevan, "Theology." (Lecture III.)

Electrical Engineers, Institution of (North-Eastern Centre), Armstrong College, Newcastle, 7.15 p.m.

Mechanical Engineers, Institution of (Yorkshire Branch), at the Y.M.C.A., Albion Place, Leeds, 7.30 p.m.

Chadwick Public Lectures, The University, Birmingham, 7.30 p.m. Sir Arthur Newsholme, "Relative Values in Public Health Work." (Lecture I.)

TUESDAY, MARCH 28. Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Papers by Messrs. E. H. Rayner, J. W. T. Walsh, and H. Buckley, on "The Lighting of Public Buildings, Scientific Methods and Architectural Requirements."

Electrical Engineers, Institution of, (North-Midland Centre), Hotel Metropole, King Street, Leeds, 7 p.m.

(East-Midland Sub-Centre), The College, Loughborough, 6.45 p.m. Mr. A. H. Seabrook, "The Future Aspect of Power Generation."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. J. W. Evans, "Earth Movements." (Lecture I.)

Anthropological Institution, 50, Great Russell Street, W.C. 8.15 p.m. Mr. H. J. E. Peake, "Bronze Swords and the Aryan Problem."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Dr. J. E. Price, "Gelatin." Anglo-French Society, Scala House, Tottenham Street, W., 6.15 p.m. M. M. Thlery, "Le Theatre d'Henry Bataille."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Dr. A. C. Guthrie, "The Advance of Medical Science throughout the Empire."

Engineers, Junior Institution of (North-Eastern Section), Armstrong College, Newcastle-on-Tyne, 7 p.m. Mr. G. H. Martin, "Utilization of Waste Heat."

Chadwick Public Lectures, The University, Birmingham, 7.30 p.m. Sir Arthur Newsholme, "Relative Values in Public Health Work." (Lecture II.)

WEDNESDAY, MARCH 29. African Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Sir E. Denison Ross, "Early Travellers in Abyssinia."

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m. Prof. E. Gosse, "Leigh Hunt."

Industrial League and Council, Caxton Hall, Westminster, S.W., 7.30 p.m. Major I. Salmon, "The Necessity for Educating the Worker in Industrial Economics."

Chadwick Public Lectures, The University, Birmingham, 7.30 p.m. Sir Arthur Newsholme, "Relative Values in Public Health Work." (Lecture III.)

THURSDAY, MARCH 30. Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Captain G. de Havilland, "The Design of a Commercial Aeroplane."

Royal Society, Burlington House, Piccadilly, W., 4 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Oriental Studies, School of, Finsbury Circus, E.C., 5 p.m. Dr. L. D. Barnett, "The Hindu Culture of India." (Lecture V.)

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. Mr. R. B. Matthews, "Applications of Electricity to Agriculture."

Chemical Society, Burlington House, Piccadilly, W., 4.30 p.m. Annual General Meeting. Address by the President, Sir James Walker. (8 p.m., Informal Meeting.)

Royal Institution, Albemarle Street, W., 3 p.m. Prof. A. M. Hind, "Landscape Etchers." (Lecture I.)

Dyers and Colourists, Society of (West Riding Section). Dr. S. A. Shorter, "The Theory and Practice of Piece Dyeing."

Brewing, Institute of (Yorkshire and North-Eastern Section). Mr. R. R. Lansdale, "Experiences in Publicans' Cellars."

Chemical Industry, Society of, at the College of Technology, Manchester, 7 p.m. Messrs. T. H. Fairbrother and A. Renshaw, "The Relation between Chemical Constitution and Antiseptic Action in the Coal Tar Dyestuffs."

Mechanical Engineers, Institution of, Storey's Gate, S.W., 6 p.m. Prof. H. H. Jeffcote, "The Milling of Screws and other Problems in the Theory of Screw-heads."

Chadwick Public Lectures, at the ROYAL INSTITUTE OF BRITISH ARCHITECTS, 9, Conduit Street, W., 8 p.m. Mr. H. E. Stilgoe, "Water." (Lecture II.)

FRIDAY, MARCH 31. Aeronautical Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7.30 p.m. Mr. Folland, "Aircraft Design."

Royal Institution, Albemarle Street, W., 9 p.m. Mr. A. B. Walkley, "Jane Austen."

Anglo-French Society, Scala House, Tottenham Street, W., 6.15 p.m. Mlle. G. Latour, "Une Heure de Poésie Moderne."

Philological Society, University College, Gower Street, W.C., 8 p.m. Prof. E. Weekly, "Names."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 7 p.m. (Students' Section.) Address by the President, Mr. J. S. Highfield.

Engineers, Junior Institution of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. J. W. Maple, "Engineering in Southern Persia."

SATURDAY, APRIL 1. Royal Institution, Albemarle Street, W., 3 p.m. Sir Ernest Rutherford, "Radio-Activity." (Lecture V.)

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday morning of the week preceding the Meeting.

FRIDAY, MARCH 31, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, APRIL 3RD, at 8 p.m. (Cantor Lecture.) GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, "The Constituents of Essential Oils." (Lecture III.)

TUESDAY, APRIL 4TH, at 4.30 p.m. (Dominions and Colonies Section.) LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, G.B.E., K.C.M.G., "New Zealand." COL. HON. SIR JAMES ALLEN, K.C.B., High Commissioner for New Zealand, in the Chair.

WEDNESDAY, APRIL 5TH, at 8 p.m. (Ordinary Meeting.) PROFESSOR ERNEST R. MATTHEWS, "Coast Erosion and its Prevention." LORD HEADLEY, M.Inst.C.E.I., in the Chair.

SEVENTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 22nd, 1922; SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Jackson, Miss Frances Agnes, Camberley.
Pe, Maung Hla, M.L.C., Rangoon, Burma.
Sarkar, M. K., Calcutta, India.
Smith, D. Curle, M.I.E.E., Kalgoorlie, W. Australia.

The following candidates were balloted for and duly elected Fellows of the Society:

Anderson, Alexander James, C.S.I., Haslemere, Surrey, and Rangoon, Burma.
East, Alan Neville, A.M.I.E.E., A.M.I.Mech.E., London.
Lloyd, Albert Lawrence, London.

MacIsaac, Donald Francis, B.A.Sc., Sydney, Nova Scotia.

Phillips, Frederick, B.Litt., Deganwy, N. Wales.
Sanders, Gerald Worsdall, Apperley Bridge, Bradford.

A paper on "The late Mr. Holman Hunt's Experiments on the Permanency of Oil Colours" was read by PROFESSOR A. P. LAURIE, M.A., D.Sc., F.R.S.E.

The paper and discussion will be printed in a subsequent number of the *Journal*.

INDIAN SECTION.

FRIDAY, MARCH 24th, 1922; SIR THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., in the Chair. A paper on "The Indigo Situation in India" was read by PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S.

The paper and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURE.

On MONDAY, MARCH 27th, MR. GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, delivered the second lecture of his course on "The Constituents of Essential Oils."

The lectures will be published in the *Journal* during the Summer recess.

BINDING COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their annual volumes of the *Journal*, cloth covers can be supplied, post-free, for 2s. each, on application to the Secretary.

The paper read was :—

LIGNITES AND BROWN COALS AND THEIR IMPORTANCE TO THE EMPIRE.

By WILLIAM ARTHUR BONE, D.Sc., Ph.D.,
F.R.S.,

Professor of Chemical Technology, Imperial College of
Science and Technology, South Kensington.

THE ORIGIN AND CLASSIFICATION OF BROWN COALS AND LIGNITES.

Coals may be conveniently divided into five principal genera, namely (A) Brown Coals and Lignites, (B) Sub-Bituminous, (C) Bituminous, (D) Semi-bituminous, and (E) Anthracitic, of which the two first are generally speaking, of more recent origin than the other three. They may all be considered as representing some stage or product of the primary decomposition and subsequent transformation of the vegetable debris of primeval forests and swamps. The process has gone on since carboniferous times in most of the great geological epochs; and, so far as its earlier stages are concerned, it is being repeated in our peat bogs and deltas, where water-logged vegetable debris is decomposing under bacterial influence.

Whilst it is not my object in this paper to discuss the origin and mode of formation of brown coals and lignites, about which there is some difference of opinion, yet a passing reference to the matter will perhaps assist us in judging of their character and value in relation to other coals. From a chemical standpoint, I can see no adequate reason for rejecting the orthodox view that they are intermediate forms between peats and bituminous coals, although our present ignorance of the subject imposes upon us the duty of expressing it guardedly as a provisional hypothesis.

The original vegetable debris from which all coals have been formed, must have consisted for the most part of ligno-celluloses *plus* a certain proportion (probably not exceeding 10 to 20 per cent.) of vegetable proteids. According to Cross and Bevan,

ligno-celluloses may be regarded as built up primarily of (1) a lignone portion, consisting of a reactive "keto R - hexene group" and a "furfurose" (*i.e.*, furfural-yielding) complex, combined with (2) α and β cellulose groups, one of which is chemically more resistant than the other. Schultze and Schuppe regard wood tissue as an aggregate of five cyclic cellulose groups ($C_6H_{10}O_5$) and a lignone complex ($C_{19}H_{18}O_8$), the ultimate composition of which would be approximately :—
C=50.0, H=5.75, and O=44.25 per cent. The debris would also probably contain, besides the foregoing main components, a certain small amount of resins, and it would be mingled with more or less mineral matter.

We must picture then vast masses of such water-logged material, first of all, decaying, either upon the actual site of its original growth (as in a peat bog) or after being macerated into a pulp and transported and deposited by water in some other low-lying swampy area. In this (which may be called the peat-bog stage) it would be subjected to the decomposing actions, both of aerobic fungi and anaerobic organisms, whose relative influences would depend upon the varying water level in the bog; with the result that the larger proportion of it would be resolved into gases (methane and carbon dioxide) and water vapour, leaving an amorphous or gelatinous humic residue comprising the more stable and resistant parts of the original debris *plus* a large amount of water. Some portion of the residue would probably be reduced to a condition of colloidal solution (*i.e.* of a *gel*), whilst the more complex and resistant part would be in a condition of ordinary admixture with, or suspension in, water. Indeed, raw peat in a well-drained bog contains as much as 90 parts of water to 10 parts of the peat substance.

In course of time, this rotted debris would either be overlaid *in situ* (during a subsequent period of subsidence), with layers of water-deposited sands or clays, or be transported by water and deposited in some other lower-lying locality, where it would be similarly overlaid with mineral matter. In either case, under the influence of a slowly increasing pressure, its water-content would gradually diminish, with the result that its combustible matter would be gradually consolidated. Under

such conditions it would be slowly transformed into something resembling the most recent types of amorphous and non-laminated "brown coals," which are of tertiary origin, and usually lie not far below the surface. They still contain a large proportion of water, in some cases as much as 50 per cent.; they are termed Earthy Brown Coals, and are quite devoid of any organic structure. As typical examples may be mentioned (a) the Morwell brown-coal deposits in Australia, about which more later on, and (b) the German brown coals, which occur in beds of either miocene or oligocene age in Saxony, Brandenburg, and in the Rhine Provinces.

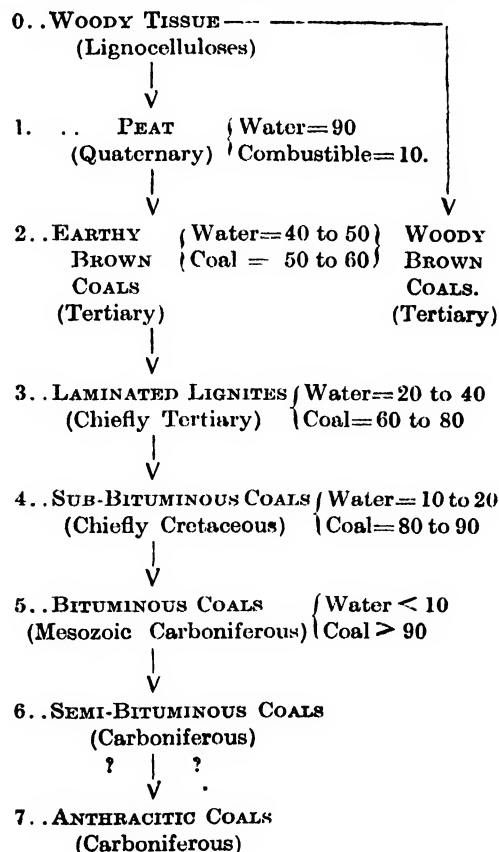

Besides such "amorphous" brown coals, and probably of similar recent formation, there are occasionally found varieties which have a very woody appearance and fibrous structure. As a good example of this class may be instanced the Valdarno deposits which occur in lower Pliocene measures in a mountain chain separating the valley of the Arno from that of Chianti in Northern Italy. Their "woody" character is so marked that they can often be sawn into pieces without crumbling. They have a chocolate brown colour, and in the raw state contain between 40 and 50 per cent. of water. Their outward appearance suggests that they have been formed from wood which, instead of having passed through the usual "peat bog" stage, has undergone a less drastic decay, not involving the disappearance of their woody character. Such fibrous brown coals are a distinct class by themselves, and may perhaps have been formed under somewhat different conditions to other varieties.

In cases where the incipient earthy "brown-coal" deposits became in course of time, buried more and more deeply under accumulations of newer mineral strata, a "blanketting" effect would be produced, with consequent gradual increase in both temperature and pressure. A similar effect would also be produced by earth-movements. This would presumably cause a partial desiccation of the coal, accompanied by certain chemical changes, affecting principally its cellulosic constituents, and resulting in a diminution of the oxygen and an increase in the carbon content of the "coal substance" itself. The deposit would thus become gradually more consolidated; in process of time it might acquire a laminated structure; and

with increasing carbon content its colour would darken. Slowly it would be transformed into the type of laminated Brown or Black Lignite which is so abundantly found in the Middle Western States of North America (North and South Dakota, Wyoming) and in the province of Saskatchewan, in Canada.

In the course of further "maturing" the lignite would acquire a shiny black colour and a well-marked conchoidal fracture; eventually it would pass into a class which is sometimes termed "*Sub-Bituminous*," to indicate its intermediate character between the true lignites and the older bituminous coals. Such types are found both in the United States and in the province of Alberta, in Canada; and they are chiefly cretaceous in origin. We thus arrive at the following provisional representation of the wood-coal series.

THE WOOD TO COAL SERIES.*

* The author wishes it to be understood that this classification is meant to be provisional only and subject to modification as further knowledge of the subject is gained.

LIGNITES AND BROWN COALS AND THEIR IMPORTANCE TO THE EMPIRE.

BY WILLIAM ARTHUR BONE, D.Sc., Ph.D.,
F.R.S.,

Professor of Chemical Technology, Imperial College of
Science and Technology, South Kensington.

THE ORIGIN AND CLASSIFICATION OF BROWN COALS AND LIGNITES.

Coals may be conveniently divided into five principal genera, namely (A) Brown Coals and Lignites, (B) Sub-Bituminous, (C) Bituminous, (D) Semi-bituminous, and (E) Anthracitic, of which the two first are generally speaking, of more recent origin than the other three. They may all be considered as representing some stage or product of the primary decomposition and subsequent transformation of the vegetable debris of primeval forests and swamps. The process has gone on since carboniferous times in most of the great geological epochs, and, so far as its earlier stages are concerned, it is being repeated in our peat bogs and deltas, where water-logged vegetable debris is decomposing under bacterial influence.

Whilst it is not my object in this paper to discuss the origin and mode of formation of brown coals and lignites, about which there is some difference of opinion, yet a passing reference to the matter will perhaps assist us in judging of their character and value in relation to other coals. From a chemical standpoint, I can see no adequate reason for rejecting the orthodox view that they are intermediate forms between peats and bituminous coals, although our present ignorance of the subject imposes upon us the duty of expressing it guardedly as a provisional hypothesis.

The original vegetable debris from which all coals have been formed, must have consisted for the most part of ligno-celluloses plus a certain proportion (probably not exceeding 10 to 20 per cent.) of vegetable proteids. According to Cross and Bevan,

ligno-celluloses may be regarded as built up primarily of (1) a lignone portion, consisting of a reactive "keto R-hexene group" and a "furfurose" (i.e., furfural-yielding) complex, combined with (2) α and β cellulose groups, one of which is chemically more resistant than the other. Schultze and Schuppe regard wood tissue as an aggregate of five cyclic cellulose groups ($C_6H_{10}O_5$) and a lignone complex ($C_{19}H_{18}O_8$), the ultimate composition of which would be approximately :—
C=50.0, H=5.75, and O=44.25 per cent. The debris would also probably contain, besides the foregoing main components, a certain small amount of resins, and it would be mingled with more or less mineral matter.

We must picture then vast masses of such water-logged material, first of all, decaying, either upon the actual site of its original growth (as in a peat bog) or after being macerated into a pulp and transported and deposited by water in some other low-lying swampy area. In this (which may be called the peat-bog stage) it would be subjected to the decomposing actions, both of aerobic fungi and anaerobic organisms, whose relative influences would depend upon the varying water level in the bog; with the result that the larger proportion of it would be resolved into gases (methane and carbon dioxide) and water vapour, leaving an amorphous or gelatinous humic residue comprising the more stable and resistant parts of the original debris plus a large amount of water. Some portion of the residue would probably be reduced to a condition of colloidal solution (i.e. of a gel), whilst the more complex and resistant part would be in a condition of ordinary admixture with, or suspension in, water. Indeed, raw peat in a well-drained bog contains as much as 90 parts of water to 10 parts of the peat substance.

In course of time, this rotted debris would either be overlaid *in situ* (during a subsequent period of subsidence), with layers of water-deposited sands or clays, or be transported by water and deposited in some other lower-lying locality, where it would be similarly overlaid with mineral matter. In either case, under the influence of a slowly increasing pressure, its water-content would gradually diminish, with the result that its combustible matter would be gradually consolidated. Under

such conditions it would be slowly transformed into something resembling the most recent types of amorphous and non-laminated "brown coals," which are of tertiary origin, and usually lie not far below the surface. They still contain a large proportion of water, in some cases as much as 50 per cent.; they are termed Earthy Brown Coals, and are quite devoid of any organic structure. As typical examples may be mentioned (a) the Morwell brown-coal deposits in Australia, about which more later on, and (b) the German brown coals, which occur in beds of either miocene or oligocene age in Saxony, Brandenburg, and in the Rhine Provinces.

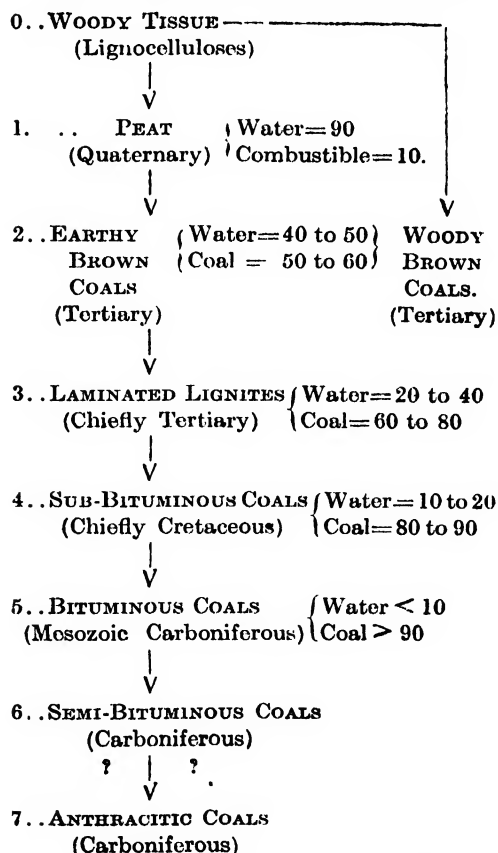

Besides such "amorphous" brown coals, and probably of similar recent formation, there are occasionally found varieties which have a very woody appearance and fibrous structure. As a good example of this class may be instanced the Valdarno deposits which occur in lower Pliocene measures in a mountain chain separating the valley of the Arno from that of Chianti in Northern Italy. Their "woody" character is so marked that they can often be sawn into pieces without crumbling. They have a chocolate brown colour, and in the raw state contain between 40 and 50 per cent. of water. Their outward appearance suggests that they have been formed from wood which, instead of having passed through the usual "peat bog" stage, has undergone a less drastic decay, not involving the disappearance of their woody character. Such fibrous brown coals are a distinct class by themselves, and may perhaps have been formed under somewhat different conditions to other varieties.

In cases where the incipient earthy "brown-coal" deposits became in course of time, buried more and more deeply under accumulations of newer mineral strata, a "blanketting" effect would be produced, with consequent gradual increase in both temperature and pressure. A similar effect would also be produced by earth-movements. This would presumably cause a partial desiccation of the coal, accompanied by certain chemical changes, affecting principally its cellulosic constituents, and resulting in a diminution of the oxygen and an increase in the carbon content of the "coal substance" itself. The deposit would thus become gradually more consolidated; in process of time it might acquire a laminated structure; and

with increasing carbon content its colour would darken. Slowly it would be transformed into the type of laminated Brown or Black Lignite which is so abundantly found in the Middle Western States of North America (North and South Dakota, Wyoming) and in the province of Saskatchewan, in Canada.

In the course of further "maturing" the lignite would acquire a shiny black colour and a well-marked conchoidal fracture; eventually it would pass into a class which is sometimes termed "*Sub-Bituminous*," to indicate its intermediate character between the true lignites and the older bituminous coals. Such types are found both in the United States and in the province of Alberta, in Canada; and they are chiefly cretaceous in origin. We thus arrive at the following provisional representation of the wood-coal series.

THE WOOD TO COAL SERIES.*

* The author wishes it to be understood that this classification is meant to be provisional only and subject to modification as further knowledge of the subject is gained.

SOME CHARACTERISTIC PROPERTIES OF BROWN COALS AND LIGNITES.

Brown coals and lignites are characterised by the following properties, which, taken together, differentiate them completely from the geologically older bituminous coals, namely in that:—(i) in the raw state they contain a large amount of water (*e.g.* generally more than 20 and sometimes even as much as 50 per cent.); (ii) on losing the same by "air drying" they usually disintegrate, either crumbling to powder or developing well-marked laminar cracks; (iii) they are devoid of coking properties; (iv) in the "dry-ashless" state they usually contain less than 75 per cent. of carbon and more than 20 per cent. of oxygen; and (v) on carbonisation at 900° they yield upwards of 45 per cent. of "volatiles." The following table shews the ultimate compositions of representative examples of the various stages in the peat-coal series:—

TABLE I.
Analyses of Typical Peats, Brown Coals, Lignites, Sub-Bituminous and Bituminous Coals.

		Irish Peat	Brown Coals.		Brown Lignite Saskatchewan	Black Lignite Malayan	Sub-Bituminous Nigerian	Bituminous Barnsley Hard Steam
			Italian Valdarno	Australian Morwell				
%	Water in the Raw Fuel	90	40 to 50	50	30 to 40	20	10	2.5
%	Ash in the Dry Fuel	4.5	5 to 10	4.0	6 to 12	6 to 10	7.5	2.75
Referred to the Dry Ashless Coal Substance.	Carbon ..	60.2	60.30	65.10	69.25	73.0	75.0	84.70
	Hydrogen ..	5.5	5.40	5.00	4.75	5.5	6.0	5.10
	N and S ..	2.0	1.95	0.45	1.70	1.5	2.4	2.25
	Oxygen ..	32.3	32.35	29.45	24.30	20.0	16.6	7.95
	% Volatiles at 900° C. ..	65	57.8	57.6	48.0	46.5	45	33.0
	(Gross Calorific) value K.C.U.s. per Kg.	5600	5800	5830	6330	6900	7625	8280

THEIR LOW GRADE CHARACTERS IN THE RAW STATE.

It will readily be understood how formidable are the difficulties encountered in utilising such low grade fuels. In the first place, their naturally high water contents, together with their tendency to disintegrate on being dried by any ordinary method, precludes their transportation in the raw state for any long distance. Next, the

fact that, owing to their low carbon and high oxygen contents, they have (even when completely dried) much lower calorific values, and yield on carbonisation much higher proportions of "volatiles" than bituminous coals, makes it extraordinarily difficult to utilise them in the raw state with reasonable efficiency for steam raising purposes in boilers. For so much heat is required to vaporise their natural water-content, that they do not give a sufficiently hot and radiating fire to ensure rapid heat transmission in boilers; also, their high "volatile" yield means that they burn with a long and smoky flame, which is not conducive to efficient working. Moreover, bad as is the natural high water content of raw lignites from a steam raising point of view, it is still worse from that of carbonising them for gas making under by-product recovery conditions. It hardly needs an experienced gas engineer to shew the

impracticability of carbonising, either in retorts or chambers, a coal containing anything from 20 to 50 per cent. of water, or to foresee the difficulties that would be encountered in attempting to recover tars and light oils from the steam-laden gas that would issue from the retorts. It may, therefore, be taken for granted that any scheme for carbonising such coals on a large scale ought at least,

to include some preliminary drying process.

Against such disadvantages must, however, be set the following compensating circumstances, namely, (i) that lignite and brown coal deposits usually lie so much nearer the surface, and are often of so much greater thickness, than those of the older bituminous coals, that the cost of mining them is, comparatively speaking, very small; (ii) that some lignites are capable of yielding, on carbonisation at low temperatures, a variety of valuable by-products comprising condensable hydrocarbons, fuel and lubricating oils, solid paraffins, etc., as well as a smokeless "fuel-residue" which can be briquetted; and (iii) that, if subjected to a suitable heat treatment (to be specified later) they may be transformed into much more efficient steam raising and gas-making fuels than might be supposed from their natural low grade characters.

How much the mere drying of a brown coal will increase its "effective" calorific power for steam raising purposes in boilers will be apparent from a consideration of the following figures relating to the Morwell Brown Coal from Australia, which in the raw state contains about 50 per cent. of water. A given weight of raw coal would, therefore, be composed half of water and half of the dry coal. Now the *gross* heat

than 84 per cent. of its gross calorific value could possibly be "effective" in the boiler. And as, in the best of circumstances, no more than about 70 per cent. of such "effectively available" heat would actually be transmitted to the water in the boiler, and, therefore, finally appear as "available steam energy," it follows that no greater boiler efficiency than about 60 per cent. would be likely to be achieved by using the *raw* coal, and it would probably be considerably less.

In this connection, it may be mentioned that in carefully measured steam trials carried out in a hand-fired Heine water-tube boiler, fitted with a Stilwell-Pierce feed-water heater, at the St. Louis Exposition, in October, 1904, by the technical staff of the U.S. Geological Survey, the efficiencies obtained using (a) Texas lignite briquettes containing 23.27 per cent. of water and 15.87 per cent. of ash and (b) N. Dakota lignite containing 38.85 per cent. of water and 10.63 per cent. of ash, did not exceed 42 and 50 per cent. respectively.*

The beneficial effects which might be expected to accrue from some preliminary drying (whether partial or complete) of such a raw fuel as Morwell Brown Coal are shewn by the following figures:—

Composition of 1 Kg. Fuel charged into Boiler.		Gross Cal. value of Fuel as charged K.C.U.s. per Kg.	K.C.U.s. avail- able for Heat Transmission per Kg. Fuel charged.	Resulting Avail- able Steam Energy assuming a 70% Transmission Efficiency.	Ratio
Water Kg.	Dry Coal Kg.	H ₁	H ₂	H ₃	H ₃ -H ₁
0.50	0.50	2800	2355	1650	0.589
0.30	0.70	3920	3542	2480	0.633
0.10	0.90	5040	4730	3310	0.657
nil.	1.00	5600	5324	3725	0.665

of combustion of 0.50 Kg. of dry fuel would be 2,800 K.C.U.s.; part of this heat, however, must necessarily be expended in vaporising the 0.50 Kg. of associated water, and another part would be rendered ineffective on account of the 0.225 Kg. of steam which is formed when the fuel is burnt. These two items would amount altogether, to 445 K.C.U.s., leaving only 2,355 K.C.U.s. as the "effective" calorific power available for transmission to the water in the boiler. Thus it would appear that, taking into account the latent heats of the water present in the raw fuel and of that formed on its combustion, no more

GEOGRAPHICAL DISTRIBUTION.

Before, however, considering further their economic utilisation, it will be convenient now to refer to the geographical distribution of brown coals and lignites, and to their importance to some parts of the Empire.

Although it would be untrue to say that the geological age of a coal necessarily determines its type and properties, yet it is nevertheless usually found that up to the "bituminous" stage the older the coal (*ceteris paribus*) the more mature is it likely to be. Thus most of the brown coals and

*U.S. Geological Survey Professional Paper No. 48, part II, Washington, 1906.

lignites are geologically of tertiary age, whilst those which I have provisionally designated "sub-bituminous" are usually cretaceous.

The tertiary brown or lignitic coals occur chiefly (i) in what may be termed the Pacific borderlands (*i.e.*, in America west of the Rockies, Japan, Australia, New Zealand, and the E. Indies); (ii) in regions adjacent to, or in continuation with, the Gulf of Mexico (*i.e.* Texas, Mississippi, Arkansas, Alabama); and (iii) in regions north of the Mediterranean, including the Central European Plain. There is also (v) a large area in the United States and Canada (comprising N. and S. Dakota, Montana, Wyoming, Saskatchewan, and Alberta) in which coal-forming conditions prevailed during the cretaceous period, and were continued in great luxuriance into the subsequent tertiary period. In this area there are now immense reserves both of "sub-bituminous" coals and lignites in the upper cretaceous and in the later tertiary formations. The "sub-bituminous" coals in this area are usually in the upper cretaceous formation.

THE BROWN COAL INDUSTRIES OF CENTRAL EUROPE.

In pre-war days the only countries which had systematically worked their brown or lignitic coal resources on any important scale were Germany and Austria-Hungary, in both of which a considerable brown-coal technology had been developed. In order to show the important dimensions to which the brown coal industry of Central Europe had attained before the War, it needs only to be stated that the German output (gross) of brown coals had increased from about 31.6 million tons per annum in 1898, to the astonishingly high figure of 87.1 million tons in 1913 (or, in other words, had almost trebled in 15 years); also, that for the year 1913 the Austrian production amounted to 27.4 million tons, and that of Hungary to about 8 million tons. Indeed, during the decade immediately preceding the War (*i.e.*, 1904-13 inclusive), the brown coal output in those regions had expanded in an even greater ratio than that of black coal, a remarkable testimony to the enterprise of our late enemies in matters pertaining to the economic development of their countries' mineral resources.

The principal brown coal mining areas in Germany are:—(1) in Saxony and Branden-

berg, where the beds are of Miocene age; (2) in the Province of Hesse, and (3) in the Rhine Province (Cologne, Bruhl, and Bonn districts) where the beds are chiefly of Oligocene age.

In the Cologne District, which may be taken as a typical example, the main deposit occurs in a large tertiary (Oligocene) bed, comprising white sands, plastic clays, and brown coals, capped by diluvial deposits. It is bounded on the S.W. by the Eifel chalk and on the N.E. by what are described as Devonian formations (shales). These tertiary beds attain a maximum thickness of 300 metres (say nearly 1,000 ft.). There are two layers of brown coal, the lower one extending over the whole area, but the upper one (which is chiefly worked) covers only a small part. The thickness of the upper coal, which is so near the surface that it can be won at a very low cost, varies between 20 metres in the South to as much as 100 metres in the North (average thickness about 27m.)

The raw coal contains nearly 50 per cent. of water. After being quarried it is subjected to a drying process in a revolving steel cylinder, about 22ft. long and 7ft. 3in. in diameter, inclined at an angle of 6° to the horizon, which is internally heated by exhaust steam passed through a series of tubes. Its moisture content having thus been reduced to about 15 per cent., the coal passes on to the briquetting factory, where it is pressed into briquettes of various sizes for domestic and industrial consumption. The calorific value of such briquettes is said to be about 4,800 K.C.U.s. per Kg. (8,640 B.Th.U.s. per lb.); and although this may seem small compared with that of a good black coal, yet, owing to their low cost of production (which in pre-war days probably did not exceed 10 marks per ton) there is no difficulty in disposing of them profitably for domestic and industrial purposes. German engineers had successfully designed boilers fitted with special types of grates for burning such brown coal briquettes, with "efficiencies" which (it was claimed) sometimes reached as high as 65 per cent. They had also developed a considerable distillation industry whereby, from the resulting crude tars, they obtained valuable burning oils and paraffin, besides a solid fuel residue.

The Austrian brown coal beds principally occur (i) in N.W. Bohemia, near the Erzgebirge borderland between Bohemia

and Saxony, where the tertiary formation runs in a direction S.W. by N.E. from the entrance of the Eger to the Elbe, a distance of 160 kilometres, and attaining in places a width of 25 to 30 kilometres, and (ii) in a broad belt of country extending on either side of a line drawn between Vienna and Trieste, and passing through the provinces of Styria, Carinthia, and Carniola.

The Bohemian lignites, which chiefly lie within 500ft. of the surface, were in pre-war days worked at a low cost by shallow shafts. In the raw state they were said to contain about 25 to 30 per cent. of water, and to be of a superior quality as such fuels go. At any rate, they were capable of supporting considerable chemical, textile and engineering industries in N.W. Bohemia. About half of the Austrian output was exported chiefly to Germany, Switzerland, and Hungary.

Time does not permit of my discussing the production of brown coal in Hungary and North Italy; but sufficient has been said to indicate how successfully the Central European peoples had developed their brown coal industries.

THE LIGNITE QUESTION IN THE UNITED STATES.

Although it is estimated that about one-third of her immense potential coal resources are lignites, it was not until the United States entered the war that she began to pay serious attention to the problem of effectively utilising them. They chiefly occur in Texas and Alabama where the beds are of tertiary origin, and in N. and S. Dakota, Montana and Wyoming, where they are chiefly cretaceous.

In the year 1918 the U.S. Bureau of Mines issued a bulletin (Technical Paper 178) setting forth the importance of scientifically developing the principal lignite fields, and pointing out that into the N. Dakota section alone, there were being imported annually from the eastern coalfields no less than 2 million tons of bituminous coals and 1 million tons of anthracites, every pound of which ought some day to be replaced by the local lignites. It was estimated that to do this would require the carbonising of about 6 million tons of lignites annually, which would yield 3 million tons of a carbonised solid fuel, 60 million gallons of tar distillates, 45,000 tons of ammonium sulphate, besides 18,000 million cub. ft. of surplus gas.

It was also suggested that in Texas, where are large iron ore deposits, with limestone near at hand, which up to then could not be smelted because of the high cost of delivering Alabama coke at the furnaces, the production of a carbonised lignite briquette at a cost not exceeding half that of Alabama coke would entirely alter the situation.

Among the specific proposals already put forward by the U.S. Bureau of Mines for the better utilisation of these lignite resources may be mentioned (i) the drying of the raw coals before use, (ii) the employment of the dried fuel in pulverised form for use in cement kilns, steam raising, and furnace operations generally, (iii) the manufacture of dried lignite briquettes for burning under boilers, and (iv) the manufacture of carbonised lignite briquettes for use in suction-gas producers and as a domestic fuel.

IMPORTANCE OF LIGNITES TO THE BRITISH EMPIRE.

Turning now to the great Federation of Commonwealths known as the British Empire, it may at once be said that, whilst Great Britain itself is almost destitute of lignites (the well-known Bovey Tracey deposit in Devonshire being the only important one), the solution of the various technical difficulties associated with their efficient use is of especial importance to Canada and Australia, as well as to other parts of the Dominions.

CANADA.—Of the estimated Canadian coal reserves, which amount altogether to no less than 1,234,269 million tons, no less than 1,072,627 million tons are of a "sub-bituminous" lignitic class, and occur in the upper cretaceous formation of the province of Alberta.

In the neighbouring province of Saskatchewan, there are two coal-bearing formations, the higher one being of tertiary age, which is comparable with the Fort Union group of N. Dakota, whilst the lower one is cretaceous. The tertiary beds are now being mined, especially in the Souris Valley, and in many places the individual seams run from 8 feet to 16 feet in thickness, and are mostly within 250 feet of the surface. The Saskatchewan reserves alone are estimated to amount to 59,812 million tons; and an investigation recently made in my laboratories upon four representative samples from the Souris Valley showed them to be of a laminated lignite class, containing

in the raw state between 30 to 40 per cent. of water, which, however, can be reduced to about 18 per cent. by "air-drying." The completely dried coals contained :—

	Per cent.	
Carbon	61.6 to 64.5	Gross calorific values 5650 to 5980 K.C. Us. per kilogram
Hydrogen	4.2 to 4.7	
Sulphur	0.6 to 0.9	
Nitrogen	0.6 to 1.0	
Oxygen	20.5 to 21.7	
Ash	6.1 to 11.2	

The Dominion Government has set up a Lignite Utilisation Research Board provided with funds to carry out researches and investigations upon such lignites, and it was through this Board's courtesy that I received the samples referred to. There can be no doubt as to the vital importance to the whole of Western Canada of a well-organised scheme of exploiting scientifically these immense tertiary and cretaceous coal resources of Alberta and Saskatchewan.

AUSTRALIA.—Extensive deposits of tertiary brown coals occur in the province of Victoria, particularly in the Gippsland and Cape Otway districts. Of these, the celebrated Morwell deposits are of phenomenal thickness, without parallel elsewhere in the world. Morwell itself lies in (or near) the Latrobe Valley, where extensive faulting took place towards the close of the Miocene period, producing enormous depressions in which large accumulations of vegetable matter were deposited evidently during Pliocene times. These originated the present brown coals of that locality. It has been estimated that within an area of 50 miles square in the Latrobe Valley, and within 1,000 feet of the surface, there are 31,144 million tons of the coal. A bore-hole put down near Morwell, disclosed no fewer than seven beds of brown coal within 1,000 feet of the surface, of a total thickness of 781 feet, the individual seams (taken in order from the surface) running 29ft. 8ins., 25ft. 8ins., 23ft., 227ft. 10ins., 265ft. 6ins., 166 ft., and 43ft. 8ins. respectively—a perfectly wonderful store of energy awaiting the service of man. So far as they have been examined, they were reported by the Victorian Advisory Committee on Brown Coal, in 1917, as consisting of "a matrix of earthy brown coal, with sporadic inclusions of lignite. . . . the matrix consists of pollen grains, spore cases, and decomposed vegetable matter The coal varies in colour between yellowish

brown and black, but it always pulverises to brown powder."

The raw coal usually contains about 50 per cent. of water. During the course of some investigations carried out under my direction upon a representative consignment of it in the Fuel Laboratories of the Imperial College, South Kensington, it was found that the *dry* coal contains :—Carbon=62.5, Hydrogen=4.85, Nitrogen=0.45, Sulphur=0.20, Oxygen=28.00, and Ash=4.00 per cent. Its gross calorific value was 5,600 K.C.Us. per kilogram.

In the year 1917 the Advisory Committee appointed by the Victorian Government to investigate the possibilities of generating electric power on a large scale from the Morwell coal reported that, notwithstanding its low grade, power could be more cheaply generated from it for the city of Melbourne than from black coal imported from New South Wales. It was officially estimated that, about that time, the cost of producing raw Morwell coal at the mines would not exceed 2s. 9d. per ton, and that it could be delivered by the existing railway in Melbourne (97 miles distant) at 7s. 8d. per ton against about 20s. for black coal from New South Wales.

According to my latest information, things are now moving rapidly on the lines indicated in the Committee's report. Large scale steam trials are in progress, with a view to ascertaining how the coal may best be burnt under boilers; a big electric power station scheme at Morwell is now materialising, with every prospect of success, and a large order for water-tube boilers in connection therewith was recently placed in this country. As the result of all these developments, it is anticipated that, in a few years hence, not only will the city of Melbourne derive the whole of its electric power from Morwell coal, but that the Victorian State railways will also be worked electrically by energy generated from the same deposits.

NEW ZEALAND.—According to the report upon the World's Coal Resources, issued by the International Geological Congress in the year 1913, New Zealand's available coal reserves are estimated at 3,386 million metric tons, of which no less than 2,080 million tons (or about 60 per cent.) are brown coals and lignites. The chief coal-bearing rocks are said to be of tertiary age, but it is thought that coal will almost certainly occur in the upper cretaceous

formations. The lignite question is, therefore, a very important one for New Zealanders, and already a start has been made with its scientific investigation. I am indebted to an official bulletin issued in 1918 by the New Zealand Board of Science and Art for the detailed results of some gas-producer and low-temperature distillation trials carried out on the native brown coals by some of its National Research Scholars. Up to then the work, although excellently begun, seems to have been rather of a preliminary character; but it will, doubtless, be duly pressed forward to completion.

INDIA.—Through the kindness of Mr. Cyril S. Fox, of the Geological Survey in India, who is now in this country, I am able to give the following particulars concerning the occurrence of lignites in that country. Mr. Fox has written as follows:—

“Beds and lenticular patches of lignite occur in association with cretaceous and tertiary strata in various parts of India. (i) Lenticular patches have been found in Ross and Viper Islands at Port Blair in the Andamans. (ii) In the Dirjum Gorge at the foot of the Abor hills and between Pasighat and Janak-Mukh in Assam. (iii) Deposits have been reported and examined along the foot hills of the Himalaya in the Darjeeling District and near Baxa and Jainti in the Jalpaiguri District of Bengal. (iv) The lignite of Ratnagiri in the Bombay Presidency has been known for some time. (v) Occurrences have been recorded from Burma, near Kindat, in Chindwin (Upper); near Talang in the Kachin hills of Myitkyina; in the neighbourhood of Kyeintali in the Arakan Hill Tracts of Sandaway; and near Hsikip and about Nangon in the South Shan States. (vi) Deposits occur in the Raipur District of the Central Provinces at Bhatagaon, Chugwa and Jumrao. (vii) The occurrences in Cannanore, Bepur and Warkali of Malabar in the Madras Presidency are important. It is estimated that 276 million tons of lignite are available in the coastal tract of Travancore. (viii) Two deposits, near Katmandu and Etaunda, occur in Nepal. (ix) Extensive beds of lignite were encountered in boring operations in the coastal tracts between Pondicherry and Cuddalore at Bahour, Aranganur and Koniakovil. The depths at which these beds, varying from 25 to 50 feet thick, occur were 275 feet, 203 feet, and 330 feet re-

spectively. An average sample analysed by Mallett gave: Carbon, 25.2%, Volatile matter, 29.1%; Water, 35.3% and Ash 10.4%. (x) The jet coal of Kalabagh in the Mianwali District and the exposures in Nerh Hill, near Murree, in the Rawalpindi District are the reported discoveries of the Punjab. (xi) Lignite occurs in several places, i.e., near Kalka, Siliani, Kalawala, Kotdwara, etc., along the Siwalik foot-hills of the United Provinces.

“The lignite beds of the Malabar Coast, particularly in the Travancore country, do not appear to have received the serious attention they deserve. The matter is the more urgent when it is appreciated that 90% of the coal production of India is obtained from the so-called Bengal Coalfields of Raniganj, Jherria and Giridih, and that the railway transportation facilities from this region are admittedly inadequate. It is only too well known that any dislocation of the coal traffic from this area, either as a result of labour trouble or other causes, seriously affects the various industries which depend on the supply of coal from the above fields. The recent establishment of great steel and iron works and the projected erection of similar larger plants in the neighbourhood of the Bengal coalfields must lead to strict economies in the utilisation of the valuable coking coals of these fields. It would, therefore, seem that the time has come for a consideration of the decentralization of the coal supply of India. By the development of other fuel resources of the country, it is possible that cheaper fuel may be obtainable in certain more distant industrial areas now dependent on Bengal coal. It is also likely that a stimulus will be given to the local commercial activity of those tracts which have peculiar industrial potentialities.”

BURMA AND THE MALAY PENINSULA.—Important deposits of well-matured lignites have been found in both these countries; but our knowledge of their resources of such coals is as yet very imperfect.

At Rawang (Malaya) a coal area has been opened out, and is being developed by the Malayan Collieries Company, Ltd. The coal-bearing series in that neighbourhood are said to consist of shales and sandstones resting on a foundation of quartzite and slates, and are thought to be of tertiary age. There are two seams, the upper of

which exceeds 24, and may possibly attain to 50 feet in thickness. Extended trials of this coal have been made with the object of testing how best it may be utilised for various purposes, such, for example, as steam raising and power-gas production. Also large-scale low temperature distillation trials have been carried out, with most interesting results, both as regards the character of the various oils and other by-products obtainable, and the manufacture of a briquetted smokeless steam-raising fuel from the carbonised residue.

The raw coal is a well-matured brown-black laminated lignite, in some respects almost "sub-bituminous" in type, containing about 20 per cent. of water. The completely dried coal contains :—

Carbon = 67.9 ; Hydrogen = 4.7 ;

Nitrogen = 1.0 ; Sulphur = 0.4 ;

Oxygen = 19.6 ; and Ash = 6.0 per cent.

Its gross calorific value (dry) is about 6,100 K.C.U.s. per kilogram, or, say 11,000 B.Th.U.s. per lb. ; and when carbonised at 900°C., it yields about 43.75 per cent. of "volatiles."

SOME GENERAL OBSERVATIONS UPON THE UTILISATION OF BROWN COALS AND LIGNITES.

For some years past I have been investigating brown coals and lignites, chiefly from a chemical standpoint, with a view to extending our knowledge of their behaviour on carbonisation at various temperatures, and of the character and amounts of the various by-products obtainable from them, and to finding out possible ways of overcoming some of their obvious drawbacks as gas producers and steam raising fuels. Some attention has also been paid to the technical possibilities of manufacturing smokeless domestic and steam fuels, as well as cokes suitable for metallurgical purposes, from the carbonaceous residue left in the retorts after carbonisation. A mass of useful data has thus been accumulated, which I hope may some day be collected in a handy form for publication ; but I fear it is impossible to compress them within the limits of the present paper. I must, therefore, content myself with a few general observations on the foregoing points, after which I propose to deal in detail with the practical outcome of some new experiments made with a view to enhancing the fuel-values of brown coals and lignites for steam raising purposes.

From what has already been said in the earlier section of this paper, I regard a preliminary drying operation as always very desirable, if not essential, to the economical utilisation of such fuels, either for steam raising or carbonisation purposes. Prolonged "air-drying" is usually capable of reducing the water content of the raw fuel down to about 15 per cent. ; but such a process is too dependent upon climatic conditions, and, moreover, takes too much time, to be generally practicable on a large scale. Consequently, other means must generally be resorted to, and it is obvious that they should, whenever possible, involve the utilisation of some convenient form of "waste-heat," such as either exhaust steam or the products of combustion from boiler furnaces, retort settings, or the like.

It can easily be shewn by calculation, that if a dried lignite be burnt under boilers, there is vastly more available heat in the gases leaving the boiler at, say, a temperature of 400° C., than would be required to completely dry the raw fuel, even if it contained as much as 50 per cent. of water. But, owing to the readiness with which dry lignites ignite, as well as to the tendency of the raw fuels to disintegrate on being dried, the problem of successfully applying the "hot chimney gases" is not without its difficulties. Our experiments have, however, shewn that such gases can generally be employed safely for the purpose, provided that they contain more than 10 per cent. of carbon dioxide, which condition should not be difficult of regular attainment on large boiler installations where the scientific control of combustion is carried out.

Provided, then, that the brown coal or lignite has been previously dried, the problem of carbonising it at any particular temperature will usually be of no greater complexity than it would be in the case of a rather low grade non-coking bituminous coal, always allowing for the circumstances that brown coals and lignites are devoid of coking properties, and that their carbonised "residues" ignite more readily than would coke if allowed, whilst hot from the retort, to come into contact with air. Their residues may, however, be briquetted with suitable binding, making excellent domestic and steam raising fuels.

Compared with those usually obtained from bituminous coals, the gas-weight and liquor

yields (referred to the *dry* coal) are generally higher, although the gas contains an unusually large percentage of carbon dioxide, owing to the higher oxygen content of the coals. The gas would certainly have to undergo some "lime" purification process for the elimination of its carbon dioxide before it would be suitable for public distribution; and even then its content of carbon monoxide would be higher than I should like to see, although my good friends in the gas industry would probably view the same with equanimity, if not with positive delight.

The question of the low temperature carbonisation of lignites is receiving attention in many quarters and is worthy of much further study. Some lignites that I have investigated yield most valuable fuel and light oils, but time does not permit of my particularising.

There is also no particular difficulty about gasifying lignites in producers, and with good results as far as the quality of gas is concerned. As an example I may here quote the results of trials carried out by the Power Gas Corporation Ltd., upon French and Italian lignites in a Mond By-Product Peat Gas Producer Plant at Orentano :—

	French Lignite (from La Savoie).	Italian Lignite (Ribollo).
	%	%

H ₂	25.6	26.3
CH ₄	5.4	4.8
N ₂	37.6	41.1
	100.0	100.0
Yield of Ammonium Sulphate in lbs. per ton of Dry Coal ..	92.5	130

In measured gas producer trials conducted under my personal supervision upon Malayan and other lignites quite as good results as the foregoing have been obtained, but they are not available for publication.

HEAT TREATMENT AT TEMPERATURES BELOW 400° C. AS A POSSIBLE METHOD OF ENHANCING THEIR FUEL VALUES.

In the course of my researches upon brown coals and lignites, I had occasion to study their behaviour when, after being previously completely dried at 110° C., they were further heated, out of contact with air, in a special form of apparatus which permitted both an easy control of the temperature condition, and the accurate measurement of any liquid or gaseous products that might be evolved.

In my first experiments on such lines, which were made upon the Morwell brown coal already referred to, some highly significant observations were made, which subsequent research has proved to be characteristic of brown coals and lignites generally. The detailed results of these researches having already been published about a year ago in the proceedings of the Royal Society, A. Vol. 99 (1921), I need now describe them in outline only, with some additional information concerning the practical developments which have since flowed therefrom.

It was found with the dried Morwell coal that, beginning at as low a temperature as 130° C., but principally between 250° and 375° C., a chemical condensation occurred, affecting the cellulosic or humic constituents thereof, which was characterised by the simultaneous elimination of both steam and carbon dioxide from the coal substance itself, without any appearance of oils or more than a quite negligible amount of gaseous hydrocarbons. Thus, in a typical experiment, when the temperature of 100 parts by weight of the dried coal was slowly raised to, and then maintained at 375° C., until no further change occurred, there were eliminated 5.5 parts of water and 6.6 parts by weight of gas (= 1427 cub. ft. per ton of the dry coal), which latter contained :—

H₂S=1.5, CO₂=88.5, CO=4.1, CH₄=1.1 and N₂=4.8 per cent.

It was thus clear that the said heat treatment had brought about a chemical condensation in the coal substance itself, possibly comparable with that by which, deep down

in the bowels of the earth, our present bituminous coals, in the course of long ages, have been slowly produced from pre-existing brown coals. Such condensations had involved a marked elimination of oxygen (as both steam and carbon dioxide) from the coal substance, with consequent considerable weight loss (amounting to one-eighth of the original) and marked increases both in the percentage of carbon content and calorific value.

The percentage composition and calorific value of the dry coal treated, and of the "residual coal" obtained were as follows:—

		Dry Coal treated.	Residual Coal.
Carbon	..	62.50	68.5
Hydrogen	..	4.85	4.9
N. and S.	..	0.65	0.8
Oxygen	..	28.00	21.2
Ash	..	4.00	4.6
		100.00	100.00

Gross Calorific
Value K.C.U.s.

per Kg. .. 5600 6360

The chemical and thermal balances of the experiment were as follows:—

		100 Parts of the dry coal containing			87.6 Parts of Residual Coal containing:-
		Parts.			Parts.
Carbon	..	62.50	yielded—		60.00
Hydrogen	..	4.85	↓	5.5 H ₂ O	4.30
Oxygen	..	28.00	↓	6.5 CO ₂	18.55
K.C.U.s.	..	560,000			558,000

It will thus be seen that whilst the dry coal had lost about one-eighth of its original weight, it had retained practically the whole of its potential heating power, but in a more concentrated form. The weight loss had amounted to about one-third of the oxygen, one-tenth of the hydrogen, but only one-thirtieth of the carbon originally present in the coal substance—a very remarkable result.

Subsequent research showed that such behaviour on similar "heat treatment" is characteristic of brown coals and lignites as a class, and that such treatment affords a ready means of "up-grading" such coals, and of improving their fuel values generally.

At this juncture I got in touch with

Mr. W. R. Wood, General Manager of the Underfeed Stoker Co., London, who had had considerable experience in burning such low grade fuels under boilers; and I put before him the idea not only of *drying*, but also at the same time of "*up-grading*" the fuel values of brown coals and lignites by further heat treatment in the aforesaid manner, in one continuous operation, using no other energy than would be comprised in the sensible heat in the burnt gases passing away from either a boiler or a retort setting. In other words, I proposed to utilise the "waste heat" of the chimney gases (assuming them to contain more than 10 per cent. of carbon dioxide and to leave the boiler at a temperature of 400° C. or more) for the purpose firstly of *drying* the raw lignite, and secondly of "*up-grading*" the dried fuel in one continuous operation, before it reaches the boiler furnace.

Mr. Wood at once saw the advantages of such a proposal, and thought it was quite a practicable one; and, at his suggestion the Underfeed Stoker Co. undertook to see what could be done to give effect to it in practice. Ultimately they designed and patented an apparatus for the purpose.

capable of being attached to a water-tube boiler. For want of a better name, I will, for the present, call it the "fuel improver" attachment, because it is designed to effect the double purpose of drying and up-grading the ingoing raw fuel at the expense of part of the heat of the outgoing products of its combustion. The following diagram shows the general arrangement of a water-tube boiler with mechanical stoker fitted with one of such attachments as designed by the Underfeed Stoker Co., which has been installed by the Victorian Government Electricity Commissioners at Morwell, and is now undergoing systematic trials there under the supervision of Mr. H. R. Harper, their Chief Engineer.

General arrangement of Boiler and Mechanical Stoker with "Fuel Improver" Attachment as installed for trial by the Victoria Government Electricity Commissioners at Morwell, Australia.

The boiler B is of the Babcock Willcox type, and is fitted with a self-contained forced-draught travelling grate stoker C; the heating surface of the boiler is 2,436 sq. ft. and the grate area is 85.7 sq. ft. The "fuel improver" attachment D is constructed of a sheet iron casing, made practically air-tight, and is fitted with two parallel series of cast-iron plates, which are sloped at an angle of about 80° with the horizontal, so as to form a chute with open sides, the plates being arranged in the form of louvers.

The raw coal is automatically fed into the top of the chute, and in slowly passing down it encounters a directed flow of the hot products of combustion from the boiler setting, whereby it is first of all dried and afterwards "up-graded" in accordance with the plan already described. In this particular installation it should be observed that the hot gases as they leave the boiler come in contact first of all with the raw incoming fuel; in other words, the relative passages of the fuel and gases through the apparatus is not on the contra-flow principle. As originally designed, it was intended that they should be on that principle; but it was afterwards thought better in this first trial unit to depart from it, because there would be less likelihood of the fuel becoming ignited during its passage down the chute if the gases met the raw fuel with its maximum water content at their highest temperature. It is hoped, however, that the result of these trials will shew this to be an unnecessary precaution, in which case the contra-flow principle will be adopted in future installations. The chute is capable of containing about 2.1 tons of raw fuel which at the present rate of operating takes about 45 minutes in passing through the apparatus.

One of the principal advantages which it is expected will be gained by the use of such a "fuel-improver" in connection with big power-station boiler installations, such as the one contemplated at Morwell, where a low-grade but cheap brown coal must be used, is that drying and "up-grading" the fuel, before it is burnt in the boiler grate, will give a much hotter and more radiant fire than it would otherwise do, with consequent increase in both the steam output per boiler and the thermal efficiency of the system as a whole. In other words, it is confidently anticipated that, owing to the higher furnace temperature which will certainly be realised when

such a fuel-improving arrangement is employed, the rate of heat transmission throughout the boiler will be greatly improved. Indeed in submitting their scheme for the Morwell contract, the Underfeed Stoker Co. guaranteed that nine boilers fitted with their new "fuel improver" attachment would give the same steam output as twelve boilers fired with the untreated fuel, and with a greater thermal efficiency.

As the trials of the apparatus are not yet completed, it would be premature for me to attempt in this paper to pass any final judgment thereon. But judging from the results which have so far been reported to me, I am able to say that it seems probable that the anticipations of the Underfeed Stoker Company will be amply fulfilled when the final results are known. For it has already been proved that, after passing through the "fuel improver" attachment to the boiler, the fuel burns very freely and can be efficiently consumed at high rates of combustion; also that the treatment of the fuel brings about a marked increase, both in the furnace temperatures and in the rate of heat transmission throughout the boiler.

Thus, for example:—

- (1) In a trial carried out on 6th October, last, in which the *raw* fuel was burnt *without being passed through the "fuel improver" attachment*, the rate of combustion in the grate was 34.9 lbs. per hour, and the water evaporated 6,550 lbs. per hour. The furnace temperature was 928° C. (1,702° Fahr.); and the products of combustion leaving the boiler at 292° C. (557.7° Fahr.) contained $\text{CO}_2=10.3$, $\text{CO}=1.7$, and $\text{O}_2=7.4$ per cent.
- (2) In a similar trial, carried out on the following day, in which the *same fuel was passed through the "fuel improver" attachment*, the rate of combustion was 94.05 lbs. per sq. ft. of grate per hour, and the water evaporated was 20,200 lbs. per hour, the furnace temperature was 1,149° C. (2,100° Fahr.); and the products of combustion leaving the boiler at 315° C. (599° Fahr.), but the "fuel improver" attachment at 92° C. (198° Fahr.) contained $\text{CO}_2=13.5$, $\text{CO}=0.33$, and $\text{O}_2=5.6$ per cent.

The foregoing figures are quoted just as they have been reported to me, but it is to be understood that they represent the results of two quite preliminary trials only,

and that no finality is here claimed for them. I am hoping soon to receive reports of further and more exhaustive trials, until which time I shall prudently reserve any final expression of opinion.

The author desires to express his best thanks to Sir Peter McBride, late Agent-General for Victoria; the Lignite Utilisation Board of Canada; the Lignite Research Company of London; Mr. W. R. Wood and the Underfeed Stoker Company, of London; the Power Gas Corporation Limited; and other friends for their courteous help in connection with the paper. He is also indebted to his colleague, Professor W. W. Watts, F.R.S., for helpful criticisms in regard to the geological matters dealt with in the paper.

DISCUSSION.

THE CHAIRMAN (Viscount Elveden) said he wished, on behalf of all those present, to congratulate the author on his most interesting and excellent paper and also on the fact that his discovery was being tried in practice. Sometimes a discovery had to wait a long time before it was put into practical use. The problem with which Professor Bone had dealt was a pressing one, because there were vast areas of the British Empire which were a long distance away from potential energy. He did not know Australia, but he did know Canada, and he knew that when one went to the vast Dominions of the British Empire, one realised how much further things were from one another there than they were in this country. If a fuel could be used that was found in the locality where it was to be employed, it was much better than if a fuel had to be used that was many days' journey by train from that place, and, therefore, it was of the utmost importance to Great Britain, to the British Empire and possibly to the civilisation of the whole world, that the energy of the brown coals with which the author had dealt should be tapped, that these coals should be brought into proper use and made to provide a source of energy for every district where they were found.

THE HON. JOHN MCWHAE (Agent-General for Victoria), said that ten weeks previously he was at the Morwell mine, and now that those present had heard a great deal from Prof. Bone upon the technical and scientific side of the subject, he would say a few words on the practical side. The people of this country were very much interested in the Morwell mine, which would be the home in the future of many thousands of English people. Australia had a population of only 5,360,000, men, women and children, but the country was a beautiful one and the climate

magnificent. Victoria was no longer dreaming of what it was going to do, but was half-way through with its plans. It was spending £8,000,000 on the Morwell coal deposits; in 1923 briquettes made from that coal would be burned, and early in 1924 electrical energy would be supplied, not only in Melbourne, but throughout the whole State of Victoria. It was calculated that energy would be furnished to manufacturers at £4 8s. 0d. per horse power and at the mine's mouth at £2 17s. 6d. Cheap power and cheap fuel meant great prosperity throughout the land. What a desirable home the State would then be for people going to it from this country—low taxation, cheap power, a magnificent climate and comparatively few people! Capitalists would be welcomed there to start new industries, and immigrants from this country could not only be settled on the land but have employment provided for them in the great industries that would be started in Victoria. Victoria intended to confine its immigration policy to British people. Australia meant to keep itself a "white country" and did not mean to let itself be filled with alien races. Ninety-seven per cent. of its people were British people and Australia was going to remain the outpost of the white race. That was why he said that British people were interested in the fact that Australia had such magnificent resources. It had, as the author said, the greatest brown coal deposits in the world. The outlook was a magnificent one with regard to coal, to say nothing of the by-products, and the people of Victoria intended to do their utmost to get as many people as possible from Great Britain to help to develop their grand and beautiful country.

DR. MARIE C. STOKES, F.L.S., said that the bituminous black coals had been the ones in which she had been more publicly interested, but nevertheless, in her laboratories, she had been very much interested in lignites and brown coals for some years, less from the point of view of their commercial value than from that of their great significance in the theory of coal formation. She would like to say a word or two on the more academic aspects of the significance of brown coals, for, although commercial and worldly prosperity was the desire of statesmen and of the nation, without vision the people perished, and the scientist had the vision which led ultimately to discovery in commercial research. There was one point in the newer lignite coals which Professor Bone did not lay great stress upon, but which was of great importance. It was on the whole, though not entirely, true that the age-maturity corresponded with the actual chemical-maturity of a coal: and that meant that the brown coals and lignites were a mass of semi-decomposed plant material of a different type of vegetation from the material which formed the bituminous coals

of the earlier geological epochs. Therefore she did not hesitate to prophesy that when at a later period, perhaps ten or more years hence, people really went in detail into the by-products of the different forms of coal, very useful *new* by-products would be found in the lignites which could not be obtained from the bituminous coals. Owing to the evolution of higher forms of plant life, new substances that at present might be too subtle for the chemist to detect were present in the lignites and brown coals, which should, therefore, be regarded not only as a source of energy, but as a source of more valuable and subtler chemical by-products. One little illustration of that might be of interest. She had had sent to her by an important Government official in New Zealand some samples of lignites from that country, and when she unpacked them she found amazingly large lumps of pure resin in those lignites such as she had never seen before, and she thought she had seen all the leading collections of coals in the world. In that feature the lignites were unique. She wished to offer a word of congratulation to the author for having been brave enough to tackle the subject of lignites. Many professors ignored their existence.

COMMANDER CARLYON BELLAIRS, M.P., said that twenty years ago he read a paper before the Royal Society of Arts on the coal resources of the British Empire, and he had listened to the present paper with the very greatest interest. He had been ignorant of the extent of the resources which had been opened up in Victoria, having only read short accounts about them in the newspapers, and it was perfectly marvellous to him to hear how those resources were being developed and would be at the disposal of the Empire. He would like to know whether the State had undertaken their development, or whether it was going to be done by private enterprise.

THE HON. JOHN McWHAE said the State was carrying out the work.

COMMANDER BELLAIRS, continuing, said he hoped the resources would be rapidly developed, and he was glad that Lord Northcliffe had devoted his attention to the question of population, because where the coal and the transport were, there the population would go. He remembered that when he wrote his paper on the coal resources of the Empire, he fell foul of Prof. Jevons's theory that the fuel resources of the world were becoming exhausted. That was a theory that so possessed Mr. Gladstone, when he was Chancellor of the Exchequer, that he brought in a Budget for getting rid of the national debt, because he said that by getting rid of its coal the country was getting rid of its capital. The first slide shown by the author, indicated that the coal resources of the world totalled over seven million million tons, and he

was delighted to see that since the time when he wrote his own paper, the resources of Canada had been calculated at between one-sixth and one-seventh of the resources of the whole world. That showed the very great wealth of coal that existed within the British Empire.

PROFESSOR HENRY E. ARMSTRONG, F.R.S., said he thought the author had brought forward two points of great importance. The first was that it was possible to get rid of the water in brown coals and lignites economically, and the second point was the work that he had done in increasing to a very great extent the fuel efficiency of those materials by preliminary heat treatment. He took it that the fact that the author's process made it possible to burn them at three to four times the rate of the raw material meant a great deal; it meant that they were fuels which could be used for purposes for which the ordinary lignites could not be used. During the last century, at all events, the people of this country had fed themselves almost entirely upon coal and there was very little else left for them to feed upon. The public did not realise that sufficiently. He thought the prospect which was being opened out in Australia and Canada was not altogether a pleasing one.

The extent to which we would be able to feed upon coal was obviously going to be materially diminished if people elsewhere could feed upon it directly and not through Great Britain; and that was what was going to happen. It was a serious matter for us at the present time, that all over the world people were learning to do their own washing and not allowing us to do so much of it for them, and this country was going to suffer very seriously thereby. Personally, he knew something of Australia, and, although he could congratulate Australia on developing in the way it was doing at the present time, he did not think the people of this country would regard with pleasure the prospect of Australia spoiling itself by becoming industrialised. He would rather that Australia retained its beauty than that it made itself hideous in the way in which this country had been made hideous.

DR. F. MOLLWO PERKIN, C.B.E., F.I.C., F.C.S., said he had examined the Morwell deposits and for sheer beauty of material he had never come across such splendid products. The amount of ash in the Morwell deposits was practically nil; they were far superior to any deposits obtained from Germany, and from what he had heard, he understood that the mining of the Morwell deposits was extraordinarily easy. He had carbonised large quantities of the coal, and had obtained most splendid oils therefrom, these oils having an extraordinarily low sulphur content.

Furthermore, the oil produced on low temperature carbonisation, say, at 480 deg. C., gave an extremely good spirit—petrol—and a good lubricating oil could also be obtained. He had briquetted the material and it formed a most excellent briquette, which produced a very small quantity of ash. The great trouble in the use of briquettes—which were often made from inferior coal—in this country at any rate, was the large amount of ash dust produced; that was a disadvantage, because the average householder did not like a large amount of ash to be deposited in the form of dust over the house. The Morwell brown coal deposit was far superior to the German; it contained about 15 per cent. of moisture, at the most, and the German very often contained up to 40 or 50 per cent. of moisture, yet the Germans were able to mine it, and to obtain a product which was commercially successful. He believed some of the German companies working these deposits had made nearly 20 per cent. profit, even with 50 per cent. of moisture. The Morwell deposit did not contain so much moisture, and it was very much more readily mined. It had got an over-burden of china clay; he had analysed the china clay, and found it was of a very good quality. He agreed with Professor Armstrong in not wishing the Dependencies of Great Britain to produce everything for themselves so that we could not sell our home products to them, but at the same time, he did not think this country wished to supply Australia with coal. It could supply Norway and Sweden with its products, and it could briquette a great deal of its raw material, the slack and dust, which at present was going to waste. Therefore, he could not see what objection this country could have to Australia developing its own resources; in fact, he thought it would be a very good thing if Australia would develop its wonderful brown coal, and Canada its lignites. He did not know that there was much brown coal in Canada, but he had seen lignites there, and he knew they were of a very good quality. The brown coal in this country—for example, in Devonshire—which the Germans were developing before the war, was not nearly so good, and yet the Germans came to England and found it worth their while to try to develop it, until the war broke out and put an end to the business.

THE HON. SIR EDWARD LUCAS (Agent-General for South Australia) said he thought the paper had been a remarkably interesting and lucid one on a topic which was certainly of very great interest and very great importance to the whole of the British Empire. The continual, and rapid diminution of our stores of anthracite necessitated on the part not only of the home Government, but of all the Dominion Governments, very great watchfulness and energy in the development of such stores of coal as there

might be in the Dominions. The Hon. Henry Newman Barwell, Premier of South Australia, would arrive in London in a day or two, and one of the objects he had in coming to this country was to find out all he could with regard to the best and latest developments in the utilisation of brown coal deposits. Just across the banks of the great River Murray, which ran through South Australia, there had been recently discovered an enormous deposit of brown coal. He thought one of the things that ought to be undertaken in every part of the British Dominions was the appointment of Royal Commissions of expert men, and women if need be, who would do what the Conservation Committee appointed by President Roosevelt did. He held the view that one of the best things President Roosevelt did for the United States was the appointment of a National Conservation Commission, and one of the most interesting reports he had ever read was the one issued by that Commission. It reported upon the national resources of the United States in regard to three things in particular—the conservation of the minerals in the United States, the conservation of the forest timbers, and the conservation of water. He thought the British Empire ought to take the matter in hand at the earliest opportunity and appoint capable men to go into the question, because great national resources were always lessening in quantity, and reports ought to be brought out as to the available supplies and the best means of conserving them. He hoped the home Government would deal with the subject in the very near future. With regard to the question Commander Bellairs had asked as to whether the brown coal deposits in Victoria were being developed by the State or by private enterprise, he would like to mention that there was not so much to fear from governmental enterprise in Australia as there was in this country. The Parliaments there were comparatively small, and the men who were sent there were much more amenable to discipline than were the 707 members who comprised the House of Commons in England. He had very great pleasure in moving a hearty vote of thanks to the author for his excellent and illuminating paper.

SIR CHARLES S. BAYLEY, G.C.I.E., K.C.S.I., in seconding the motion, said he would like to add a most hearty vote of thanks to the Chairman. He was a little disappointed that nobody had spoken about the brown coals and lignites of India. Besides being very much interested in India generally, he happened to be the Chairman of the Indian Section of the Royal Society of Arts, and it would have given him great pleasure to hear some remarks about products, coals and lignites of that country, which apparently existed from Nepal and the Darjeeling district down to Bombay. He hoped that

somebody would be found to take the matter up for the benefit of India.

The resolution was carried unanimously.

PROFESSOR BONE, in reply, said his difficulty in preparing the paper had been not what to put in, but what to leave out. The subject was a very wide one, and, although there was much that had yet to be learned about it, sufficient was already known to form the subject of a course of lectures. He would have liked to have the opportunity of giving further particulars of the work that had been done on the by-products obtainable from the various coals he had described; perhaps on another occasion he might be able to do so. He had tried to draw attention in the paper, not only to the extreme importance of the subject to the Dominions from a commercial aspect, but also to the necessity of having it thoroughly investigated on scientific principles, now that its development was still in what might be called the initial stage. He quite agreed with Dr. Stopes as to the value of scientific research, properly directed, in the case of such problems as that under discussion, provided that it was taken up *ab initio*, when the whole subject was in its early stages of development. He, therefore, hoped that when the Governments concerned took up the question of the commercial exploitation of the coal and lignites, they would not forget the importance of having it thoroughly investigated in all its scientific aspects, so that the latest knowledge and research might be brought to bear upon it. If they neglected that they would neglect a very important duty. He, therefore, wished to plead for the proper scientific investigation and development of the immense potential resources of brown coals and lignites which occurred in almost every part of the Dominions.

The meeting then terminated.

MR. CYRIL S. FOX sends the following addition to his note incorporated in Professor Bone's paper:—The vast lignite deposits of Saskatchewan in Canada and the great beds of brown coal in Victoria in Australia, have already been investigated and found capable of profitable development. It is true that the unpalatable fact has been discovered that no successful method of briquetting lignitic coals without a suitable binding material appears to be known outside Germany and that, as a result, the Dominion Government contemplate erecting plant on the American system of carbonising their lignite to 600° C., and briquetting it with a binding material of coal tar pitch. They estimate a production of 100 (short) tons a day. The Commonwealth Government, on the other

hand, appear to have negotiated with Leitz and Co., of Halle, for direct briquetting plant. They contemplate at first an output of 96,000 tons of briquetted brown coal a year, although they estimate that the smallest successful commercial plant should utilise six presses capable of turning out 300,000 tons of briquettes a year. The cost of the smaller plant is estimated at £86,000 plus another £264,000 for boilers, buildings, conveyors, electrical plant, etc.—giving a total of £350,000. The cost of the larger plant is estimated at a total of £750,000. The question of size of the briquettes has been discussed. Small sizes, 2 to 8 ozs. each, are recommended for local consumption and larger briquettes, up to 2 lbs. weight each, for export purposes.

Some idea of the German developments in the use of briquetted fuel may be gauged from the fact that the Lauta Aluminium works in East Germany are to be supplied with 60,000 kilowatts of electrical energy which will be obtained from briquetted lignite. The full significance of this can only be appreciated when it is understood that the *sine qua non* of the electrolytic production of aluminium is cheap power—so far invariably obtained from very favourably located hydro-electric projects. There are likely to be many possible demands for the briquetted lignite from the Travancore littoral supplies for the coastal shipping; for the South Mahratta Railway through Marmagao; for various potential chemical industries, such as the establishment of cement works, the purification of bauxite in the production of alumina, the manufacture of magnesium sulphate from bitterns, the preparation of fish manure, etc.—if the lignite proves suitable for direct briquetting and can be prepared cheaply for supply to the west coast of India.

In many ways the Travancore area appears to offer an attractive field for investigation. At present little is known. There are said to be nodular accretions of resinous matter in these lignites which may prove of economic importance in a subsidiary way. But a full preliminary examination of the area is urged. If the results are encouraging, attention may later be turned to the buried resources of the Trichonopoly District of Madras and to other tracts of India. A French company was floated to work the Pondicherry area, but a "hitch" which occurred was purely a financial one. It is to be regretted that these areas have not received the attention they deserve. The question becomes more pressing each year, and now that briquetting is an established method of marketing friable fuels, and the Froth Flotation process for cleaning and drying low grade coals has been shown to be both economical and advantageous, it is evident that the time is ripe for a re-investigation of some of the more favourably located occurrences of Indian lignite.

All reference to the occurrence of peat in India has been omitted in this note. It is questionable whether the term peat is applicable to the accumulations of vegetable matter which have been reported as peat in Lower Bengal and in the Lake District of Kumaon and in Kashmir. These deposits are not considered as of any economic importance.

Large areas of true peat are, however, known to occur in the Nilgiri Hills of South India. The bogs in which this peat is found occur at elevations above 6,000 feet. Fifty years ago (see *Journal Society of Arts*, Vol. XIX., 1871, pages 201 and 266) recommendations were made by a Col. R. Wraage for utilizing this fuel on the Madras railways. This peat was used as fuel in Ootacamund, but difficulty appears to have been experienced in drying it sufficiently. The question of development does not seem to have been re-opened.

CORRESPONDENCE.

SURFACE COMBUSTION.

My attention has been drawn to a statement made by my friend Professor H. E. Armstrong (on p. 305 of your issue for 10th March, 1922) in the course of a discussion on Mr. E. V. Evans's recent paper before your Society upon "Some Solved and Unsolved Problems in Gas Works Chemistry," which I think calls for some correction. Professor Armstrong, in referring to a particular application of my well-known discovery of flameless incandescent surface combustion, formerly known as the "diaphragm" but now as the "radiophragm" method of heating as applied to grilling and roasting operations, said that "unfortunately the flame lit back."

I think Professor Armstrong must have here spoken under some misapprehension, and I therefore wish to place on record the following statement with a view to putting the matter right.

The original radiant surface combustion "diaphragms," as designed by my late collaborator, Mr. C. D. McCourt and myself, and manufactured in Leeds to our instructions, did not back-fire when run on explosive mixtures of the then coal-gas and air, and when freely radiating according to the conditions which they were designed to meet. Such diaphragms were normally kept running for the whole day in our experimental station at Leeds without any signs of back-firing; and they were exhibited and demonstrated in various parts of Great Britain, America, and Germany with never a complaint of the kind referred to. I have still one or two of the old diaphragms by me, which were made in accordance with our original specification, and they do not back-fire, even when used on present day gas.

There are admittedly conditions under which such diaphragms can be made to back-fire,

e.g., if their free radiation is so impeded as to allow of too great an accumulation of heat in the incandescent layer, which is the seat of the intensive combustion. Moreover, if diaphragms are made of an unsuitable grade or character, and not in accordance with the original specification, it is not unlikely that back-firing will occur. Possibly it is this latter circumstance which may have lent some colour to Professor Armstrong's suggestion. But if the diaphragms are properly made, in accordance with the original specification, and used under conditions for which they were originally intended, there will be no back-firing trouble.

In connection with the subject of these "radiophragms" (as they are now termed) I may perhaps be allowed to add that, largely owing to the patient efforts of Mr. F. J. Cox, the technical manager of Radiant Heating Ltd. (the original company formed to pioneer my surface combustion inventions), considerable improvements have recently been made in the manufacture of the diaphragms, whereby they can now be made of a uniform grade and texture in large quantities. They are now being largely used, not only in hotels and restaurants for grilling and cooking purposes, but also in confectionery and biscuit factories, and the demand for them is rapidly developing, because of their remarkable radiant efficiency, and of the fact that the explosive mixture of gas and air in the proportions for theoretical combustion is burnt intensively in the incandescent surface under conditions which can be perfectly controlled.

WILLIAM A. BONE.

PRODUCTION OF BLACKSTRAP MOLASSES IN CUBA.

The principal dealers in Cuban blackstrap molasses state that a fair average analysis of this product will show 10 to 17 per cent. water, 36 per cent. Clerget sugars, 16 per cent. glucose, and the remainder fibre, gums, and salts, the last named being by-products which are not now utilized.

It is claimed, says the United States Vice-Consul at Havana, that under an efficient process the average gallon of blackstrap molasses will distil from 0.3 to 0.5 gallon proof alcohol. It would, therefore, appear that few products are better adapted to the manufacture of alcohol. Producers and dealers in the Havana district express the opinion that the demand for blackstrap molasses will steadily increase, especially if alcohol comes into general use as a substitute for petrol in running motors. Moreover, it is believed that the growing demand for the use of raw molasses in the manufacture of certain stock foods will offset the loss of the market occasioned by the prohibition of the manufacture of alcoholic beverages in the United States.

Owing to the high price of sugar as compared with that of molasses, the latter product is often burned by the sugar mills as fuel in connection with other refuse, instead of being stored until shipment can be made. A proper interest in the storage and conservation of blackstrap molasses by the sugar mills depends largely on the offering of a fair market price; and if excessive profits are gained by any of the parties handling the product, the margin will become too narrow to be profitable to the others.

A more careful conservation would also create a demand for steel storage tanks both at the sugar mills and various points of shipment. It is stated that the port of Matanzas has storage capacity for over 16,000,000 gallons; Havana, 8,000,000; Cienfuegos, 6,000,000; Santiago de Cuba, Monaco, Lucaro, Antilla, Nuevitas, and Puerto Padre 2,000,000 to 3,000,000 gallons each; Boqueron, Caibarien, and Sagua under 2,000,000 gallons each. Important improvements are under way at Matanzas and it is believed that additional storage will soon be available at that point. Approximately 765 tank cars of 5,000 gallons each are held by shippers of molasses, and the United Railways have available some 40 tank cars of less capacity.

The estimated production of molasses in 1920 was 180,000,000 gallons.

HYDROGENATION OF OILS IN JAPAN.

The hardening of fish and vegetable oils by hydrogenation is a comparatively recent industry in Japan, having been started in 1912, with one factory under foreign management. Originally the industry was intended to furnish hardened oils for soap making, but owing to recent developments there is now a small surplus for export. The extent of the trade may be estimated by the fact that in 1918 hardened oil amounting to 788,673 pounds, valued at about £19,000, was exported, but in 1919 and 1920 the exports evidently were smaller, as hardened oil was not listed as a separate item in the customs returns for those years.

According to a report by the United States Vice Consul at Kobe, there are now eight plants in Japan manufacturing hardened oil by the hydrogenation process, with a combined capacity of 62 tons per day. The raw materials used by most of these plants are whale and fish oils, although a few also harden vegetable oils (principally coconut and soya bean), or fish and vegetable oils mixed. Some of the plants obtain their hydrogen used by the decomposition of water by electrolysis, which can be done profitably in Japan, where electric current developed by hydro-electric plants is plentiful and reasonably cheap. Others use hydrogen obtained as a by-product from the manufacture of caustic soda, or by the action of acids upon metals. The processes employed in most of the factories are not made public, but it is known

that one concern uses a Japanese patent similar to the German Wilbuschwitch patent, and another has the sole right to the Ellis patents in Japan.

The Japanese soap industry, which furnishes the principal market for the hardened oil, has tripled in size during the past ten years, and in 1919 the output amounted to some £3,000,000. This quantity not only supplies domestic needs but leaves a surplus valued at about £400,000 for export. In 1920, 2,000,704 dozen cakes of toilet soaps and 6,928,380 pounds of laundry soaps were exported, principally to China, India, the Dutch East Indies, and other parts of the Far East.

The hardened oil industry has developed with and is dependent upon the soap industry for its prosperity. As a result of the severe trade depression, consequent upon deflated prices and the breakdown of foreign trade, the market for soap has decreased considerably, with a corresponding decrease in the home demand for hardened oil. At the same time the market abroad, which formerly absorbed the small surplus, has practically disappeared. Consequently, producers of hardened oil in Japan have had a bad period, although most of them are still operating. No improvement can be expected in the industry until trade conditions in general, and the oil and soap markets in particular, show indications of settling down. The hardened oil industry in Japan, adds the Vice-Consul, should develop considerably in the future, as Japan has abundant supplies of fish and vegetable oils and a steady market at home for part of the output.

A NEW FLAX SEED

Attention is drawn in the *Times Trade Supplement* to the production of a new pedigree flax seed by Dr Vagas Eyre, the director of the Linen Research Association Institute, near Lisburn. He has discovered, among the fresh varieties of flax seed which his scientific methods of fertilisation produced, two of the Livonian strain, which on being tested yielded 80 per cent. more fibre than any other seed on the market, while the quality of the fibre was on the average two grades higher. In fact, taking these two items into consideration, it is not an exaggeration to state that the return is 100 per cent. better than from the Dutch flax seed hitherto grown. An increased return of this order would not only mean a larger supply of raw material fibre at a low cost, but according to Mr. J. G. Crawford, a well-known linen manufacturer, more easily spun yarns of a more uniform quality. Hence the importance of this discovery to the linen industry.

Naturally, the production of this pedigree seed in any quantity will take time. It required years before from one single pickle there was evolved one pound weight of seed, but the work was patiently continued until now there

are approximately five tons available. Its further distribution and commercialisation is under consideration, and while a portion will be given to careful Irish flax growers, another quota will be developed at the National Institute of Agricultural Botany at Cambridge, while the remainder will be sent to Canada, where climatic conditions are favourable for seed development.

GENERAL NOTE.

INDIA OFFICE LIBRARY—The annual report of the India Office Library for the financial year 1920-21 shows that there were 3,001 readers, while 1,888 books were taken away on loan and 67 MSS. and xylographs lent. The accessions numbered 7,581, of which 3,401 were issues of periodicals. There were also received 632 Archæological Survey photographs, 6 gramophone records of dialects spoken in Delhi; 37 transcriptions and translations of gramophone records of languages spoken in the Central Provinces and Berar; Tibetan MS. fragments (transferred from the British Museum); 4 Tibetan xylographs; 10 Arabic MSS., 1 Persian MS., MS. Journal of Major-General James Welsh, 1845-48; 84 Siamese books (presented by the Vajiranana National Library, Bangkok), etc. The pre-war exchanges with foreign institutions and societies have in a great measure been restored. Amongst the donees of books in the 12 months under notice were the Preussische Akademie der Wissenschaften (Berlin) and the Bibliothek der Bayerischen Akademie der Wissenschaften (Munich). The printing of Professor Keith's catalogue of Sanskrit MSS. was postponed for reasons of economy.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 p.m. (unless otherwise announced):—

APRIL 5.—**PROFESSOR ERNEST R. MATTHEWS**, "Coast Erosion and its Prevention." **LORD HEADLEY**, M.Inst.C.E.I., in the chair.

APRIL 26.—**JOHN FRANCIS CROWLEY**, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry." **SIR JOHN F. C. SNELL**, Chairman of the Electricity Commissioners, in the chair.

MAY 10.—**MAJOR PERCY A. MACMAHON**, R.A., LL.D., ScD., F.R.S., "The Design of Repeating Patterns for Decorative Work." **SIR CHARLES CARRICK ALLOM** in the chair.

MAY 17.—**OSWALD M. SHEPARD**, "Recent Developments in Rubber Manufacture, with special reference to Rubber Machinery and the Manufacture of Tyres."

MAY 24.—**GEORGE FLETCHER**, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

MAY 31 (at 4.30 p.m.)—**LAWRENCE HAWARD**, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock:—

APRIL 28.—**F. G. ROYAL - DAWSON**, M.Inst.C.E., "The Need for an All-India Gauge Policy." **SIR ROBERT WOODBURN GILLAN**, K.C.S.I., LL.B., in the chair.

MAY 26.—**SIR THOMAS W. ARNOLD**, C.I.E., D.Litt., M.A., Professor of Arabic, School of Oriental Studies. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced:—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION

TUESDAY, APRIL 4, at 4.30 p.m.—**LIEUT. COLONEL SIR THOMAS BILBE ROBINSON**, G.B.E., K.C.M.G., "New Zealand." **COL. HON. SIR JAMES ALLEN**, K.C.B., High Commissioner for New Zealand, in the chair.

FRIDAY, JUNE 9, at 4.30 p.m.—**MAJOR SIR HUMPHREY LEGGETT**, D.S.O., R.E., "Tanganyika Territory (formerly German East Africa)."

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETING.)

Friday afternoon, at 4.30 o'clock:—

MAY 5.—**PROFESSOR WILLIAM HENRY ECCLES**, D.Sc. (London), F.R.S., "Imperial Wireless Communication."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, "The Constituents of Essential Oils." Three Lectures. March 29, 27, April 3.

Syllabus.

LECTURE III.—APRIL 3.—The Derivatives of Benzene. Alcohols. Acids and Esters. Aldehydes. Phenols and their derivatives. Heterogeneous Compounds. The Trend of Modern Research. The importance of the Essential Oil Industry to the British Empire.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, APRIL 3.—Geographical Society, 135, New Bond Street, W., 8.30 p.m.
Farmers' Club, at the Surveyor's Institute, 12, Great George Street, S.W., 4 p.m. Mr. R. B. Matthews, "The Uses of Electric Power in Agriculture."
Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. Messrs. E. R. Sutcliffe and E. C. Evans, "The Effects of Structure on the Combustibility and other Properties of Solid Fuels."
Electrical Engineers, Institution of (Western Section), Swansea, 6.30 p.m.
British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. S. C. Ramsey, "London Clubs."
Royal Institution, Albemarle Street, W., 5 p.m. General Meeting.
Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. H. Bentham, "Fractures in Concrete."

TUESDAY, APRIL 4.—Royal Institution, Albemarle Street, W., 3 p.m. Prof. J. W. Evans, "Earth Movements." (Lecture II.)
Alpine Club, 23, Savile Row, W., 8.30 p.m. Mr. G. A. Solly, "British Mountaineering: its Development and Contrasts."
Marine Engineers, Institute of, 85, The Minories, E.C., 6.30 p.m. Sir D. Wilson-Barker, "Animal Life at Sea, including all Living Things generally seen, with Notes on Flight."
Civil Engineers, Institution of, Great George Street, S.W., 6 p.m.

VOL. LXX.

FRIDAY, APRIL 7, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

EIGHTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 29th, 1922, SIR ROBERT ARMSTRONG-JONES, (C.B.E., M.D., F.R.C.P., in the Chair.

The following candidates were proposed for election as Fellows of the Society :

Morgan, N. L., B.Sc., Quebec, Canada
Pillay, G. Hurry Krishna, M.B.E., Rangoon, Burma.

Rayner, George Jabez, Victoria, British Columbia.

Kamla, Pat Sahai, London

Starr, Mrs. Ida M. H., Easton, Maryland, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:

Roberts, Alfred Edwin Priestland, Birmingham.

Vardy, William Andrew Shakespeare, Northampton.

The Shaw Lecture on "Alcohol in Relation to Industrial Hygiene and Efficiency" was delivered by Sir Thomas Oliver, LL.D., D.Sc., M.D., F.R.C.P.

The lecture and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURE.

On MONDAY, APRIL 3rd, MR. GUY RADCLIFFE, M.Sc.Tech., F.I.C., Lecturer in Applied Organic Chemistry, College of Technology, Manchester, delivered the third and final lecture of his course on "The Constituents of Essential Oils."

On the motion of Mr. F. Lewis, a vote of thanks was accorded to Mr. Radcliffe for his interesting course.

The lectures will be published in the *Journal* during the Summer recess.

DOMINIONS AND COLONIES SECTION.

TUESDAY, APRIL 4th, 1922 ; COLONEL THE HON. SIR JAMES ALLEN, K.C.B., High Commissioner for New Zealand, in the Chair.

A paper on "New Zealand" was read by LIEUT.-COLONEL SIR THOMAS BILBE ROBINSON, G.B.E., K.C.M.G.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING

WEDNESDAY, MARCH 1st, 1922.

MR. PERCY A. SCHOLES, Music Critic of the "Observer," in the Chair.

THE CHAIRMAN said that Mr. Emanuel Moor, on the plea that he could not speak English very well, had asked him to give a description of the Duplex-Coupler Pianoforte, which was the subject of the meeting that evening. Personally he had not invented the piano and he had not even seen the inside of it, but he had heard it played, and some weeks ago Mr. Moor had explained it to him. He had also read two articles in the "Times" on the subject, an excellent article by his friend and colleague, Mr. Ernest Newman, in the "Musical Times," and a lengthy and very instructive article in "Music and Letters" by Prof. Donald Tovey, the Professor of Music at Edinburgh University. From those various sources he had gathered the following information. The Duplex-Coupler Piano was designed to do away with a great many of the present difficulties in piano playing. He was sure many people would welcome it on that account, because not only would it enable them to play the piano more easily and better, but it would do away with a great

deal of their neighbours' children's practising. There were many passages—passages difficult to stretch, passages of jumps, passages of octaves—which became perfectly simple when played upon the Duplex-Coupler piano. As far as he could judge from his small knowledge of the instrument, what it did was to bring distant things nearer together. It had two keyboards, but only one set of strings and one set of hammers. When one played upon the lower keyboard one played upon a normal piano and one need not use the upper keyboard at all, but if one used the upper keyboard an advantage was obtained from the fact that the upper keyboard played an octave higher than the lower or normal keyboard. Supposing, for instance, he wanted to play the note C and the E ten notes higher, instead of trying to grasp that extended interval on the one keyboard he could take the two notes quite close together upon the two keyboards. The two keyboards were so cunningly adjusted to one another that it was perfectly easy to play with one hand upon the two at the same time. He could play with his thumb on the lower keyboard and with any of his fingers on the upper keyboard; the C and E ten notes apart could be played three notes apart quite easily. The use of the two keyboards would also obviate the left-hand jumps that were such a trouble to the girl next door when playing a waltz. The instrument was so contrived that the two keyboards could be coupled together. The difficulty of playing passages in double octaves was well known; quite a lot of time was spent by the student in learning to play those octaves well and nobody could play them well in the sense of playing them really smoothly. With the two keyboards of a double keyboard piano coupled, however, which was done by depressing a pedal, single notes could be played which immediately became octaves, because a C, for instance, on the lower keyboard had a C an octave higher on the upper keyboard coupled to it. One could play simple little scales and be playing octaves all the time, and they could be played as smoothly as scales of single notes could be played on an ordinary piano. When a difficult piece of music was turned into an easy piece, something more was done than merely ministering to the natural laziness of people. They were enabled to play more artistically; their minds were no longer concentrated on

conquering difficulties, but they were able to devote themselves to artistic performance. From his own personal point of view the great advantage of the Duplex-Coupler Piano was the following: He was tired of hearing difficult piano music played because it was difficult and of hearing it received with applause because it was difficult; he wanted to hear piano music played because it was beautiful and expressed something and he wanted to hear it received with applause for the same reasons. He had, as part of his daily duty, to attend concerts, and it was impossible for anyone to attend concerts as frequently as he did without studying and criticising not merely the performers and the composers whose works were being played, but also the audiences gathered to hear them. In every audience that came to hear, say, a piano concerto one found a number of people who were enjoying the music not because it was fine music, but because it was difficult to play or they imagined it to be so. He remembered hearing a piano concerto played a month or two ago and he had in front of him a little family party of about six people, who had one pair of opera glasses amongst them and passed them from hand to hand; they were there evidently to watch the pianist, and they were there to watch him as they would be in a music hall to watch a clever gymnast. When piano makers, instead of putting their own names on the side of their instruments, put there the name "Emanuel Moor," that would be a sign to everyone in the hall that the difficulties in the music that was being played had been overcome, and he hoped that the interest of watching instead of listening would also be at an end, to the great advantage of musical art. All he feared and he hoped Mr. Moor would be able to remove his fear was that the difficulties of playing the existing music having been overcome by Mr. Moor, fresh difficulties might be invented by cunning and diabolically-minded composers in order that a fresh race of pianists might astonish future generations upon the double keyboard piano, as the existing and past races had astonished this generation and their forefathers upon the present piano. He had not had the opportunity of questioning Mr. Moor on that point, and he would like to be completely satisfied about it. He would leave the meeting that evening feeling immensely cheered if he was assured

that Mr. Moor had not only abolished a great many of the difficulties in existing music, but invented an instrument which was not capable of producing a fresh crop of showy difficulties which would cause pianists still to continue to be looked at instead of listened to.

The following address was then delivered:

THE DUPLEX-COUPLER PIANOFORTE.

BY EMANUEL MOOR.

The idea of this piano came into my head more than twenty-five years ago, but when I described it to various makers and musicians they all shrugged their shoulders as though the last word had already been said on the subject of pianoforte construction. I was, therefore, greatly discouraged, as inventors in other branches of science and art have often been. Two years ago, about 4 o'clock in the morning, I had a very vivid kind of dream that I was playing Bach. A great deal of Bach's music was written for an instrument that usually had two manuals and a pedal. Directly after I had had this vision I rose and dressed and went to a little farm that we owned, where there was an old upright piano, and I immediately investigated the question as to whether the mechanism could be adapted to have two keyboards. I found it could, so a few days later I issued a pamphlet explaining all the possibilities which the Chairman has just described to you. This pamphlet did not help me very much, as every piano maker in Europe, and even in America, to whom I sent it, rejected the idea and said it was not possible to construct such an instrument. I was, therefore, obliged to obtain the help of two carpenters, and I installed myself in our farm and managed to make a piano that would play. Of course, it had not the perfection of a machine-made instrument, because a piano is a very exact and precise mechanism, but when I had got so far that the instrument gave out sounds I got a pianoforte manufacturer at Berne to come and see it. He said the idea was very good, but when I asked him to give an estimate of the cost of making such a piano he said he could not do so. However, three days later he wrote to me, saying that he was very interested in the whole idea, and if I would give him a share in the patents he would construct the piano for nothing.

Of course, that meant a great saving of money to me, and we had this model made that is in this room now. A good many critics in Zurich and Basle wrote about it, and some of their articles reached Prof. Tovey, who came to see me last August. I did not know him before, but when he saw the piano he asked to be allowed to stay in our house for several weeks to learn it. He was kind enough to interest the musical critic of the "Times" in the matter, and that gentleman also came to see it. In that way news of it reached England, and the Aeolian Company approached me and came to an arrangement with me, and thus first instrument that you see here was imported. The pianos that will be constructed now in England will be much superior to this one.

MR. MOOR then gave a demonstration of the duplex coupler piano, showing the advantages of the two keyboards—the notes on the upper keyboard being an octave higher than the corresponding notes on the lower keyboard—and of the arrangement for coupling the two together. He also showed that by the operation of a certain device the piano could be turned into a harpsichord, so that very good effects could be obtained in that way when playing classical music which had been conceived and composed for an instrument which had a richer sound than a piano. The old music had been written to a great extent in two parts, and two-part music when played on an ordinary piano sounded rather empty, the harmonies and so on being subdued.

MR. MAX PIRANI then played on the duplex-coupler piano a Prelude and Fugue by Bach, from the original organ edition.

THE CHAIRMAN said that Mr. Moor set out not as an inventor but as a composer. He was not an inventor who, instead of inventing a new sort of wireless apparatus or motor car or sewing machine, turned his thoughts to music, but he was a composer who, feeling the need for other means of expression and better facilities for self-expression as a musician, had discovered those means and those facilities. People in this country did not as yet know much of Mr. Moor's music, though a few years ago several of his symphonies were played at the Queen's Hall and the famous Fonzaley Quartet had played a concerto by him. He wished to emphasise the fact that Mr. Moor had approached the subject as a musician and not as an inventor.

MISS WINIFRED CHRISTIE then played a Sonata by Scarlatti in E major and a Bach Prelude, using the harpsichord device.

THE CHAIRMAN asked if the harpsichord tone was produced by the interposition of a small body of metal between the hammers and the strings.

MR. MOOR said that was so. The present was a temporary device but it answered the purpose for the moment. The real point would be that with the tiny hammers there would be great precision. If a metal string was plucked as in the harpsichord the effect was not as good as it was in the present case. Some conservative people might think it was, but in reality it could not be so, because the friction never gave quite such a clear tone as when the strings were struck by the hammers. The friction was enough to enfeeble the sound. The two instruments had been compared and it had been proved that his was the better.

It was pointed out by a member of the audience that the gauge of the modern piano string was larger than the gauge of the harpsichord string, which would make a difference in the quality.

MR. MOOR said his intention was not so much to imitate the old harpsichord as to create a new sonority resembling that of the old instrument, but capable of producing piano and forte effects.

It was also pointed out that the true harpsichord mechanism could not produce the same intensity of tone as the hammer mechanism, and that the piano provided possibilities of expression which the harpsichord could not give, because the latter was purely mechanical.

MISS CHRISTIE then played Brahms' Capriccio in B minor, not using the harpsichord device.

THE CHAIRMAN said the following questions had been handed to him in writing: "Prof. Tovey points out in 'Music and Letters' that the new instruments are likely to have very great improvements. Will there be a sub-coupler for lower octave as well as a super-coupler? Also, will it be possible to strike any one note on both the lower and the upper keyboards simultaneously?"

MR. MOOR said it was not proposed to have a sub-coupler.

THE CHAIRMAN said he did not see that there would be any advantage in having one, as it did not matter whether octaves were played as super-octaves or as sub-octaves.

MR. MOOR agreed. With reference to the second question, an arrangement for that would ultimately be made: it was only a question of expense.

MR. PIRANI then played some passages from Liszt's "Campanella," an Organ Prelude by Bach in G major, and the Fugue that followed it.

In answer to a question as to whether there would be any possibility of having stops in the duplex-coupler pianoforte when the harpsichord arrangement was being used, the chief charm of the harpsichord being in the combination of different stops, which gave totally different effects, MR. MOOR said it would be possible, but it would greatly increase the cost. In the case of the piano differences of sound could be obtained by altering the touch, whereas in the harpsichord that was not so. It was not desirable to have too many resources, as it was possible to have too many intermediary effects from a musical point of view.

In answer to a question as to whether the weight of touch was the same whether one keyboard was being used or the two coupled, MR. MOOR said when the keyboards were coupled the touch was slightly heavier, because two hammers had to be put into action, but it was not so heavy as it would be if two notes had to be struck. The slight heaviness was really an advantage, because quite a new impulse was obtained. The touch was obviously not very heavy, because a chromatic scale could be played very quickly.

In reply to a question as to whether all existing music would have to be re-fingered for the duplex-coupler piano, if that piano was to be used by students, MR. MOOR said the fingering would have to be changed in a way, and THE CHAIRMAN said that point had been dealt with by Prof. Tovey in his article in "Music and Letters." Prof. Tovey deprecated the bringing into existence of a new notation or a new system of fingering. He supposed that students would be taught how to adapt their music to the two keyboards if they thought they could obtain a better effect by the use of two keyboards. If a new system of notation was brought out, the music publishers would have to produce all the music in duplicate.

MR. MOOR said there was one further point he wished to mention. On the organ the same piece by Bach or Handel could be played in the same style with quite different registration, and people who went to hear organists playing were delighted if the registration gave some variety. In the case of the ordinary piano, the player could introduce differences in spirit and temper and feeling, but as far as the actual mechanical resources were concerned, they did not permit of any sort of variety. The Duplex-Coupler Piano, however, enabled a player to register the music in different ways and to obtain some results which it was absolutely impossible to obtain with an ordinary piano.

Miss CHRISTIE then played a Gavotte by Gluck on the harpsichord and a piece by Rosenthal.

MR. G. K. MENZIES (Secretary of the Society) said that it was the custom at the Ordinary Meetings for the Chairman to propose a vote of thanks to the reader of the paper. In the present instance, however, at least 50 per cent. of the lecture had been given by the Chairman, and it was hardly possible for him to propose a vote of thanks to a dual entity of which he himself was quite a half. He (the speaker) therefore took upon himself to propose a very hearty vote of thanks to Mr. Scholes and Mr. Moor for the duet which they had given, and also to Miss Christie and Mr. Pirani for their admirable and artistic demonstration of the instrument.

The resolution was carried unanimously, and, the Chairman having briefly responded, the meeting terminated.

ELECTRICITY AND AGRICULTURE.*

In England and Wales there are 418,000 farms and small holdings, five-sixths of which are of less than 150 acres in extent. The problem of increasing the yield of all these undertakings is of the utmost importance to the welfare and safety of the country. According to the author's experience, it is possible even in our own climate to raise much more food, reduce waste and failure, and stabilise the conditions of the Agriculturist by the use of electricity on the farm.

Great progress in this direction has been made in America and Canada, and upon the Continent, whilst in our own country there are already some notable developments as in the district of Hereford and certain parts of Wales.

The farm, and particularly the small farm, is not an ideal situation for machinery needing skilled attention; it is usually also impossible to supply it with gas and costly to provide coal or heavy fuel. Electricity which can at once be used to give light, heat or drive machines is obviously the simple and flexible form of power service needed on the land, being so easily conveyed by overhead wires, without disturbance of the surface, and free to leave the line of the roads for any point where its services are needed.

The speaker put forward information upon the cost of using electricity for all general operations around the farm buildings, the saving to be effected by employing electric light in cowsheds, the improvement in cleanliness, reduction in waste of milk, cattle food, and other materials by removing the dark and difficult conditions which exist during a large portion of the year in these buildings. He showed also how readily an electric motor can be applied to driving

different machines, for chopping cattle food, operating churns, milk separators, etc. These motors are entirely covered in from dirt and moisture, need no skilled attention, and can be moved about from place to place according to the work in hand, season of the year, etc.

More extensive applications of this form of power are applied to the ploughing of the land, whilst in other directions we find, as so often happens with the employment of electricity, that the incidental savings and economies resulting from it far outweigh any question of cost. For instance, it has already become the practice to dry hay artificially by means of electrically-driven fans. This gives the farmer much greater control over his crops, and makes him more independent of the weather. In other districts there are records of the use of electric heating for the prevention of frost amongst stores of roots and vegetables, whilst already it is employed extensively for the drying of fruits in bottling factories and similar undertakings.

It is stated that in New Zealand over 9,000 farms are fitted with electric milking apparatus, which requires very little power, reduces the number of persons in charge, and goes a long way to provide the necessary cleanliness in handling milk.

So far the application of electricity on the farm is largely a matter of employing methods which have already been tried and found successful in manufacturing industries. A safe and adaptable form of light easily installed in any building, old or new, a flexible means of driving machines independent of the use of fuel, the production of smoke, heat and fire risk, naturally commends itself to the farmer, who has once seen it in operation and can get the necessary supply of power, particularly so as experience shows that the actual amount of power required across the year is a very small matter on the farm; but in addition to this it is obvious that we may expect remarkable further developments as electrical engineers give more and more attention to these problems.

Already the use of electric heat has been successfully employed for incubation. Electric light has been shown capable of increasing the yield of eggs, or at least increasing their yield during that period of the year when they are of the highest market value.

Other applications of electric power full of promise relate to the sterilization of milk, the treatment of green fodder preserved for winter use by the method known as ensilage, and last, but not least, there is a wide, and as yet but imperfectly explored, field, electro-culture. It has been known for a long time that plant growth could be stimulated by the discharge of electricity at very high tension in its neighbourhood, although the precise reason for this is yet comparatively obscure. Recent experiments on a practical scale have, however,

*Abstract of paper read by Mr. R. Borlase Matthews before the Institution of Electrical Engineers.

demonstrated that an extremely small amount of electrical power converted in suitable apparatus to a very high tension and discharged from overhead wires strung across the fields has a remarkable effect upon most forms of vegetable life, increasing their yield, and in many cases advancing the period of harvest. Although it is at least possible that this effect may be rather in the nature of a stimulant than a food, and due to some effect upon the plant which enables it to pick up nutriment from suitable land more successfully than it could do unaided, yet there is already sufficient evidence to justify careful and continued research in this direction.

AGRICULTURE IN SOUTH AFRICA.

Since the early days of settlement fruit and vegetable farming has been of vital importance to the white people of South Africa. At first, they were compelled by force of circumstances to grow fruit and vegetables for their own consumption, and later on they undertook the culture of the vine. Afterwards the production of wheat was found possible, and from those early beginnings eventually developed the main industry of South Africa, for, until the development of diamond and gold mining, the Union was exclusively agricultural and pastoral.

Although South Africa has surpassed all other countries in the production of diamonds and gold, yet farming actually remains the industry of the people and the industry that offers the largest scope for development. The aggregate value of the agricultural products of the Union already exceeds that of mining, and with the agricultural resources of the country so little developed at the present time remarkable progress will undoubtedly take place in the future. The following particulars of the industry are extracted from an interesting report on the subject by the U.S. Consul at Johannesburg:—

Nearly all farms in South Africa are large. Small holdings, except near the cities, are uncommon. In consequence, a large proportion of the land is uncultivated, and there still remain vast areas which have never been touched by the plough. As a rule, a large part of each farm is set aside as pasturage, and farming and cattle raising go hand in hand in nearly every instance.

The principal crops grown in the Union are maize, wheat, oats, kaffir corn, rye, barley, tobacco, cotton, and forage. Tea is also produced to a limited extent in Natal; and the cultivation of sugar is confined almost entirely to that province. Maize is actually the leading crop, and, in fact, South Africa is now recognised in the principal markets of the world as one of the foremost fields for the production of maize of good quality.

On account of favourable climate and suitable soil maize is produced almost throughout the

Union. However, the maize belt is often defined as the country lying east of the 26th meridian, which may be traced by drawing a line between Algoa Bay, Bedford, Cathcart, Queenstown, Aliwal North, Wepener, and Bloemfontein, and thence north to Lichtenburg and Zeerust. The Transvaal is the largest producing Province of the Union, but the Orange Free State holds the record for growing the heaviest crop per square mile.

The production of maize has increased considerably in recent years. Besides supplying the local demand, 509,495,794 pounds were exported in 1918; however, in 1919 exports declined to 246,265,197 pounds. On the other hand, wheat is not grown in sufficient quantity to meet the requirements of the country.

Oats hold a more important place than wheat in local agriculture. However, oats are not always grown for grain, but instead find a ready market in the form of food for horses and cattle. The yield averages from 17 to 24 bushels per acre.

As applied locally, the term "kaffir corn" includes both kaffir corns and durras. The former are indigenous to South Africa, and comprise the original red and white varieties, as well as the varieties improved from seed obtained from the United States. The durras are of North African origin, and include brown, white, and yellow durra. They are both non-saccharine sorghums. Kaffir corn is not only important as a foodstuff for the native (coloured) population, but it is also employed as a substitute for maize in feeding cattle.

The principal forage crops are lucerne, teff grass, and manna. The first-named is the most important, and wherever water can be procured this plant flourishes in nearly every part of South Africa. It is a hardy perennial of rapid and luxuriant growth, and under favourable conditions can be cut several times a year. Lucerne is peculiarly adapted to irrigation farming in semi-arid parts, and with the development of irrigation in the Union and the expansion of the live-stock industry its cultivation will undoubtedly increase. Besides being used to an increasing extent in the milk, butter, and cheese industry, as well as the pig industry, lucerne is also likely to become a more important supplement to veld grazing in the development of the beef export trade.

Tobacco is grown in various parts of the Union of South Africa, but the principal producing areas are the Magaliesburg and Kat River districts. In these two sections a light and medium tobacco of the Virginian type is produced; and in the Potchefstroom, Vredefort, Pietretief, Oudtshoorn, and Piquetberg districts a medium to heavy type of tobacco is grown; while in the Stellenbosch, Wellington, and Tulbagh areas a Turkish tobacco is found. Natal also produces a medium dark tobacco, which is largely employed in the manufacture of cigars and partly

in the manufacture of a cheap-grade tobacco for pipes.

The average yield of bright tobacco in South Africa is approximately 800 pounds per acre, while that of dark tobacco is about 1,000 pounds per acre.

The tobacco and tobacco manufacturing industries have experienced considerable change in the class of leaf and manufactured article required by the public during the past 10 or 15 years. Formerly a heavy type of tobacco was used, but now a light cigarette tobacco leaf is consumed more extensively. In the early days the principal demand was for dark and medium tobacco suitable for ultimate conversion into pipe tobacco and snuff. At that time, a fairly large percentage of each year's crop was put up by farmers into roll tobacco, the rolls being converted into pipe or snuff tobacco by the consumer. This practice still exists to some extent.

During more recent years factories for the manufacture of cut pipe tobacco and cigarettes have been established in the Union, and, in consequence, an increasing demand for tobacco of light or medium colour and fine or medium texture has arisen. This factor has encouraged the production of a leaf suitable to the manufacture of cigars. The production of colonial Turkish leaf has also been firmly established, and cigarettes are now made from locally grown Turkish tobacco.

Although the production of cotton was first attempted in South Africa about 50 years ago, success did not attend the efforts of the early planters, chiefly on account of labour and transportation difficulties, but partly on account of the lack of cultural knowledge. The Union Government undertook a series of experiments to determine the possibilities of growing cotton in South Africa. As a consequence, new interest in this industry was awakened, and now there are approximately 8,000 acres under the cultivation of cotton in the Rustenburg district, 2,000 acres in the Waterberg district, 100 acres in the Tzaneen section, 50 acres in the Transkei district, and 4,000 acres in Natal.

Planting takes place during October and November, and the picking begins in April and continues until June or July. In the Rustenburg district, the largest cotton-producing area in the Union, the best results have been obtained from the class of cotton belonging to the big boll group. The average yield is 250 to 300 pounds of lint per acre. In some sections where light frosts occur growers practise "ratooning," that is, they permit the plants to stand for two or more years instead of ploughing the land each year and planting again. The yields are, as a rule, better from "ratooned" fields, and the lint does not appear to be of a lower quality. In any event, this method of cultivation decreases materially the cost of production, but it can be practised under favourable conditions only.

Ginning is done chiefly in the Rustenburg, Pretoria, and Lydenburg districts, and also upon the Maboki estates and at Tzaneen as well as in Natal. The gin at Rustenburg has a capacity of approximately 8,000 pounds of lint per day, and those at Pretoria and Maboki can deal with 3,000 pounds per day.

The surplus cotton-seed is generally used as food for cattle. The seed is delinted, and ground into meal without being decorticated. The production of cotton-seed oil has not yet assumed any importance, but with the expansion of cotton planting it should develop accordingly.

Tea is grown principally in the Province of Natal, where it thrives best at an altitude of 1,000 feet. It was first planted as an experiment at the Durban Botanical Gardens in 1851. For a long period the industry was conducted along experimental lines, but afterwards developed into a commercial enterprise. It progressed rapidly until 1911 when the restrictions on emigration imposed by the Indian Government began seriously to hamper the industry by taking away a source of cheap and plentiful labour. Although there is at present approximately £350,000 invested in this industry, the tendency is to abandon the cultivation of tea in favour of sugar.

The production of sugar cane for the manufacture of sugar is confined to Natal and Zululand, although its culture can be carried on in Rhodesia and over a great part of Portuguese East Africa. The total area under cultivation in 1916-17 was 163,000 acres. The quantity produced was, however, insufficient to meet the requirements of the country.

Although favoured with unusual conditions tending to promote its expansion, South Africa's fruit industry is still in its infancy. However, the magnitude which it may eventually assume can be gauged to some extent by taking into consideration the large number of varieties of fruit which experiments have already proved can be successfully produced upon a commercial scale, the long season of growth which is opposite to that of the northern hemisphere, the geographical position of South Africa with respect to the European markets, and the highly developed steamship service existing between the Union and the British Isles and Europe. The principal fruits grown upon a commercial scale are apples, apricots, avocado pears, bananas, cherries, custard apples, Cape gooseberries, figs, granadillas, grapefruit, grapes, guavas, lemons, limes, litchis, mangoes, olives, oranges, pawpaws, peaches, pears, pineapples, plums, quinces, and strawberries.

The consumption of fruit is very large in the Union, especially in the mining districts, and the export trade is increasing.

The seasons being reversed, the markets of Europe and North America are available to exporters of South African fruit. Fresh fruit is plentiful in the Union when it is almost

unprocurable in England and at a period of the year when competition is at a minimum in the United States. For almost half of the year South Africa has no nearer competitor in the European market than the Australasian Colonies and certain parts of South America. In addition, it is connected with the United Kingdom by a regular steamship line, besides being served by less regular sailings. The arrival of fruit on the European market in first-class condition is rendered possible by the provision of cool chambers, suitable for fruit traffic.

That South African fruit can be placed upon the European and North American markets is evident from the following dates of ripening, arranged according to seasons, which are not so clearly defined in the Union as in the United States :

November —Figs, apricots, strawberries, peaches, pineapples, bananas, and pawpaws

December.—Apricots, plums, peaches, strawberries, pineapples, bananas, and pawpaws

January.—Strawberries, peaches, plums, grapes, early pears, apples, pineapples, bananas, pawpaws, pears, and mangoes

February.—Peaches, nectarines, grapes, plums, melons, pineapples, bananas, and mangoes

March and April.—Grapes, late apples, pears, peaches, and pawpaws

May and June —Guavas, pineapples, bananas, Cape gooseberries, oranges, naartjes, lemons, avocados, walnuts, and chestnuts.

July to October —Oranges, lemons, naartjes, grapefruit, limes, loquats, pineapples, and bananas

The production of citrus fruits was in the past confined to comparatively small areas and the total income derived annually therefrom was of slight moment, but in recent years new and increasing interest in this industry has been awakened, and now it promises to assume far-reaching importance. The area of land on which citrus fruit will thrive is large, and for this reason, as well as on account of the favourable conditions tending to promote the development of this industry, an increasing amount of capital is being invested in citrus and other non-deciduous fruit plantations.

The orange is the principal citrus fruit cultivated in South Africa. It can be grown in every Province of the Union and practically throughout Rhodesia, although no large groves yet exist in the Orange Free State, notwithstanding the name. Many different varieties of oranges are grown, but the tendency is to restrict cultivation to those which are suitable for the export trade. Seedlings, which represent approximately 75 per cent. of the bearing trees in the country, are found all over South Africa.

Naartjes (mandarins) also thrive in the favourable climate of the Union, but this class of fruit has not yet proved sufficiently popular in the European markets to warrant extensive

cultivation. Grapefruit has never been grown on a large scale, and as an export fruit lemons have not succeeded in competing with the product of Southern Europe and California. Other citrus fruits are the lime, cumquat, shaddock, and citron.

The culture of the mango in South Africa is comparatively of recent origin and hence the South African export trade in this fruit is inconsiderable. The mango is grown to greater perfection in the Barberton district of the Transvaal than in any other part of the Union. However, Natal produces mangoes in greater quantity than the Transvaal, although the fruit is frequently of low grade.

Much more profitable is the growing of pawpaws, which are highly appreciated throughout South Africa. This fruit, which is among the most healthful to eat, is very delicate, and conditions at the present are such as to preclude any large amount of exports.

As an ornamental plant or adjunct to the garden for the sake of its foliage the banana is found over a great part of South Africa, but it is produced commercially in Natal only. Even in that Province the banana is not extensively cultivated, and the total production barely meets the requirements of the Union. A fruit greatly appreciated but produced upon a small scale solely for domestic consumption is the avocado, or alligator pear, which also is grown in Natal and the warmer parts of the Transvaal.

Like other fruits of a more or less tropical character the pineapple thrives in Natal, the Eastern Province of the Cape of Good Hope, and certain parts of the Transvaal, but in the Transvaal irrigation is generally employed in order to obtain perfection inasmuch as the clear and dry climate does not contain sufficient moisture to enable the pine to make successful growth. All that is conducive to the production of pines of the finest quality, as regards both soil and atmospheric conditions, is to be found in the lower Albany district. Here more planting has taken place in recent years than in any other part of South Africa, and this district is the largest producing area in the Union. That the pineapple industry bids fair to develop upon a sufficiently large scale to permit of a good-sized export trade being built up is evident from the new capital seeking this outlet. One company acquired recently a large estate for the purpose of growing pineapples and other fruits.

Apples of good quality are grown in many parts of the Union, the chief centres of culture being the Eastern and Western Provinces of the Cape, the Orange Free State, Transvaal, and the highlands of Natal. On the high, cold veld of the Orange Free State there are some of the largest and best developed orchards in South Africa. The fruit is not only of good size and appearance, but possesses an excellent

flavour. The quality of the fruit grown in the Transvaal, which is similar to the Orange Free State as regards altitude and climate, is equally good, while the Western Province of the Cape possesses the oldest trees in the Union. South African apples make an excellent dried fruit, and this phase of the industry is gradually assuming more importance.

The pear is more extensively planted in the Western Province of the Cape than in any other part of South Africa. It is the leading export fruit and in flavour, size, and appearance is highly regarded upon the European markets. The Asiatic type of pear also grows widely in the hotter parts of the country, but it is not so popular on account of inferiority in flavour and texture.

Peaches of many varieties are to be found all over South Africa, but, as in the case of pears, climatic conditions, dependent principally upon altitude, determine the type of peach to be cultivated. The high veld is suitable for peaches commonly grown in Europe and North America; while the low and bush veld is adapted to peaches of Chinese origin. The Western Province is probably the largest producing area, but the peaches grown on the high veld are superior in quality. This is notably the case in respect of the vicinity of Johannesburg, where peaches of almost unsurpassed excellence are grown. Peaches of good quality always command high prices in the local market, and to some extent they enter into the supply of both canned and dried fruit.

Nectarines grow best on the high plateaus of the interior, while apricots attain the greatest perfection near the sea. The Western Province is the most important producing district for both fruits. The fig not only thrives in the Cape Province, but also does exceedingly well in the Transvaal, where its cultivation upon a commercial scale is very limited. On the other hand, there is a fairly large trade in plums, especially in the Western Province, which is the leading centre for the production of deciduous fruit. The type of plum which flourishes best in South Africa is of Japanese origin, the export trade being almost wholly confined to this class.

The grape vine was introduced into South Africa as early as 1653, and to-day it is found growing all over the Union. Certain districts are, however, better adapted than others to the cultivation of the vine owing to climatic influences, and, in consequence, the chief centre of culture can be given as lying between 33° and 34° south latitude. The yield of the vine is probably as high in South Africa as in any country. Besides serving as a table fruit for both domestic and foreign consumption, grapes are used to a very large extent in the local manufacture of wine and brandy.

Of the berry and bush fruits, the strawberry, raspberry, loganberry, and "Cape" gooseberry grow in abundance. They are cultivated

chiefly for the purpose of supplying the local demand and to a smaller extent for canning and the making of jam.

The wild olive is found throughout South Africa, but all attempts to establish a successful industry have failed so far. The principal drawback to the industry is said to be the presence of the "olive fly," an insect well known to the olive-growing countries of Europe. While this is a deterring factor in the development of the industry in South Africa it does not by any means preclude the successful growing of olives in that country.

RESOURCES AND TRADE OF THE SANTA CRUZ DISTRICT OF BOLIVIA.

The Department of Santa Cruz, possessing a total area between 367,000 and 376,000 square kilometres, is situated in Eastern Bolivia. It is bounded on the west by the Departments of Cochabamba and Chuquisaca, on the north by the Department of El Beni, merges on the south into the unexplored plains of the Gran Chaco, and is bordered on the east by the great Brazilian State of Matto Grosso.

The Department is divided into the seven Provinces of Cercado, Sara, Cordillera, Vallegrande, Nuflo de Chavez, Velasco and Chiquitos. The provinces of Sara, Cercado, Nuflo de Chavez, and Velasco consist largely of plains that are an extension of those of the Beni, and this area of low country is connected with the plains of the Province of Cordillera by the belt of the Monte Grande, which lies between the Guapay and the San Miguel to the east of Santa Cruz. The plains of the Province of Cordillera are in turn only a continuation of the vast "llanuras" of the Chaco.

Though most of the Department lies outside the region of the Andes, the Province of Vallegrande is a rough district lying among precipitous ranges, which rise in places to a height of nearly 10,000 feet. In the eastern parts of the Department a broken series of low hills run in a south-easterly direction across the Chiquitos country from the region of the Guarayos to the Rio Paraguay below Corumba. There are many valleys and pockets among these hills with considerable extensions of agricultural and pasture lands.

Most of the area of the Department is drained by tributaries of the Amazon system. The eastern section is drained by affluents of the Paraguay, which runs close to the frontier. The Rio del Curiche Grande, a tributary of the Paraguay, separates the department from Brazil for some distance above Puerto Suarez. In the south-western part of the Department the mysterious Rio Parapiti crosses the province of Cordillera, where through parts of its course it spreads out across the plains in the wide "Cañados" or marshes of Isozo, and finally disappears in the sands of the Chaco.

The climate of the Santa Cruz region varies from sub-tropical to tropical, the climatic gradations depending on the diversity of altitude and of latitude. There is little rainfall between July and November, but there are heavy rains from November to March, and rain may also fall in April, May and June. The rainfall is heavier in the low-lying Provinces of Cercado, Sara, Nuflo de Chavez, and Velasco than in those of Vallegrande and Cordillera and in most of Chiquitos, though there are occasional torrential rains in the outlying ranges of the Andes and in the hill country of Chiquitos. In some years there is a dearth of rain in Cordillera, especially in the parts bordering Chaco; however, there is usually a plentiful supply of sub-surface water which could be easily reached with artesian wells.

The winter coincides with the time of least rainfall, and the summer is the season of heaviest rainfall. The average yearly temperature at Santa Cruz is about 25° C. The winter temperature generally ranges between 11° and 22°, and the summer temperature usually varies from 25° to 35°.

In most districts the climate is notably healthful, though the habits of the natives are extremely insanitary. Malaria is prevalent in certain parts, as in some of the Chiquitos valleys, and there have been occasional outbreaks of dysentery and smallpox, but in general health conditions compare very favourably with those any part of South America. Some districts, as about Santiago de Chiquitos, have an almost ideal climate.

The city of Santa Cruz, which was built in 1560, is the political capital and commercial centre of the Department. It lies about 3 kilometres from the Rio Pirai at an altitude of 1,380 feet above the sea level, and is situated in the midst of a great plain, across which a network of roads leads in every direction. In 1900 Santa Cruz had a population of 18,335 people, which at present probably amounts to 20,000.

Most of the construction work in the City is of plaster and wood, and the houses generally have porticoes in front for protection against the heat. The streets are unpaved and deep in sand when they are not flooded by torrential rains which fall during the summer, and are lighted by oil lamps. When the resources of the surrounding region are developed Santa Cruz will undoubtedly be one of the most important inland cities of South America.

According to a report by the United States Trade Commissioner, in Bolivia, from which the following particulars are extracted, the problem of communication with the outside world is one of prime importance to the economic life of this remote part of the Republic. At present there are four principal trade routes from Santa Cruz, leading respectively, to the north, the east, the south, and the west. To

the Beni there is a cart track as far as Cuatro Ojos on the Pirai during the rainy season, and as far as Las Juntas or Puerto Velarde, at the junction of the Pirai and Grande, during the dry season. The distance from Santa Cruz to Cuatro Ojos is about 90 miles, and thence to Puerto Velarde is another 30 miles. In the wet season the road is very bad in the forest of Cuatro Ojos for a stretch of several leagues, and beyond that it is a veritable bog. Cuatro Ojos and Puerto Velarde are, respectively, the limits of launch navigation on the Mamore system during the wet and dry seasons. Launches ply down the Mamore by Trinidad to the terminus of the railway at Guajaramirim.

This route is undoubtedly destined to be of increasing importance to the Santa Cruz country and is at present the only practicable road for the importation of bulky merchandise. Pieces weighing 2,000 to 2,500 pounds, and probably more, could be brought in by this route. Goods can be shipped directly to Santa Cruz by consigning to the Madeira-Mamore Railway Co. at Para or Manaus, or to the Amazon Steam Navigation Co. at Para. The Madeira-Mamore interests now have an agent in Santa Cruz. Such consignments should be marked "Para despachar a Santa Cruz, Bolivia."

One of the most famous routes in Bolivia is the old cart road between Santa Cruz and Puerto Suarez, which was laid out by Suarez Arana between 1874 and 1879, and which connects the interior of the Republic with the Parana River. This road, between 690 and 700 kilometres long (1 kilometre—0.621 mile), crosses the Rio Grande a few miles out of Santa Cruz and then disappears into the wilderness of the Monte Grande. For about 135 kilometres it is a narrow track cut through the forest, with four pickets of soldiers at intervals of a day's ride. After leaving the Monte Grande the road skirts the marshy Lake Concepcion and then passes through San Jose, the capital of the Province of Chiquitos. Thence it leads below Santiago and by the village of Santa Ana to Puerto Suarez on the Laguna de Caceres, from which communication is had by a narrow channel with the Rio Paraguay.

During most of the year the lagoon, though large in extent, is too shallow to admit vessels of the draft which ply between the River plate and Corumba. At such times it is navigable only for launches drawing from 1 to 2 feet of water, and the channel is often obstructed by great floating beds of weeds. It is sometimes necessary to unload goods on to carts at Puerto Sucre, between Corumba and Puerto Suarez, for transportation to the latter point. For probably two months of the year, when the Paraguay is at its height, steamers which reach Corumba and which draw 5 or 6 feet of water are able to enter the Laguna de Caceres and discharge their cargo at Puerto Suarez.

The route between Corumba and Puerto Suarez followed by the launches is about 10 miles in length.

Long stretches of the eastern road, especially across the low country between the last of the Chiquitos hills at the Carmen ranch and Puerto Suarez, are flooded during the rainy season and converted into almost impassable bogs for considerable distances. Myriads of mosquitoes and other small but extremely annoying insects torment the traveller who makes this trip in the rainy season. On the other hand, during the dry season, which is at its height in September and October, there is a serious scarcity of water over this stage of the road, and travellers are dependent for water for themselves and their pack animals on the precarious supply which they may encounter in the water holes at intervals of many leagues along the roads.

The traffic over this road is by means of mules, oxcarts, and bullocks. Mules, which are often difficult to obtain, reach Santa Cruz in about three weeks from Puerto Suarez. Oxcarts drawn by five or six yoke of oxen cover the distance in from 35 to 40 days when the road is at its best, but after the annual rains have begun they may require from 6 to 10 months for the journey, being held up for weeks at a time by swamps and swollen rivers. Considerable travelling is also done on the backs of bullocks, whose splay feet prevent them from miring in the deep mud and sand through which much of the road lies.

This road has lost most of its importance as a route for the importation of foreign goods into Santa Cruz, and practically all the merchandise sent out of Puerto Suarez is distributed among the towns of the intervening region, such as Santiago and San Jose, or is diverted from the main road into the country to the north.

The road from Santa Cruz into Argentina leads south and to the east of the last foothills of the Andes, to which it runs roughly parallel, and reaches the frontier at Yacuiba, thence continuing to the terminus of the Argentine Central Northern Railway at Embarcacion, a distance of 879 kilometres from Santa Cruz. Most of the traffic over this road is by means of mules, though oxcarts are also used for some classes of merchandise. At certain times of the year there is a lack of water over some of the southern stretches.

The most important road from Santa Cruz is that which connects with the plateau and the Pacific by way of Cochabamba. This road passes through the towns of Samaipata, Pampagrande, Chilon, Totorá and Arani, and thence across the valley of Cochabamba to the end of the railway from Oruro at Cochabamba. From Santa Cruz to Totorá the road can be used only by mules, but from Totorá to Arani is open for automobile traffic during the dry season. From Arani into Cochabamba, a distance of 66 kilometres, there are daily trains over the narrow-

gauge railway of the Empresa Luz y Fuerza Electrica Cochabamba. However, mule trains between Santa Cruz and Cochabamba do not break their journey between these two points. The total distance of about 470 kilometres is covered by mule in from 12 days to 2 weeks, and Totorá can be reached from Santa Cruz in 9 or 10 days. Each mule will carry about 5 arrobas, equivalent to about 200 pounds, and the charge for freight is from 45 to 60 bolivianos per mule. From the edge of the plain, a few leagues outside of Santa Cruz, nearly to Arani, the course of the road is through a rugged mountain region, some of the roughest country lying among the last Andean ranges in the vicinity of Samaipata. There are several precipitous climbs and descents, and travelling is difficult during the rainy season, when the track is muddy and slippery and the streams are full.

There have been several projects for giving the Santa Cruz region a railway outlet to the Paraguay River. In 1889 an English firm proposed to the Bolivian Government to build a railway from Puerto Pacheco to Sucre, and another from the Laguna de Garba into the Itenez country, but nothing came of these proposals. In 1900 a Belgian company presented proposals for a line from Bahía Negra to Santa Cruz, including an ambitious programme for the development of eastern Bolivia. The concession granted to this company expired in 1914, similar proposals having been made meanwhile by Italo Argentine interests. Recently certain Brazilian interests have made overtures to the Bolivian Government for the prolongation of the North-western Railway of Brazil from Porto Esperanza by Corumba and Puerto Suarez to Santa Cruz. Construction of such a line should be easy, as grades would be negligible and in no part would there be required cuts or fills of over 5 metres (1 metre 3.28 feet) in depth.

There have also been several projects for a railway line to connect Santa Cruz via Yacuiba with the Argentine system of lines. At present a project is on foot for the building of a railway from Sucre to the lower Pilcomayo with an outlet to the Rio Paraguay at Formosa over the Argentine State Railway, which is being extended north-west to Embarcacion. This project is connected with the plans of American interests for the development of the oil fields in the Lagunillas district.

Alternative destinations for a railway from Santa Cruz to the plateau are Cochabamba and Sucre. General opinion favours the route from Cochabamba. The further development of eastern Bolivia is absolutely dependent on the establishment of better communications with the outside world. This project would afford not only a more satisfactory outlet for the products of the Santa Cruz region, to the markets of the more thickly populated plateau, but access to foreign markets as well.

The building of railway lines from Cochabamba and the Paraguay River would give the needed impulse to the great industrial possibilities of the eastern part of the country in such products as sugar, cotton, cattle, tobacco, petroleum, lumber and other products. Moreover, it would supply the necessary link for the completion of a trans-continental line from Santos to Arica. A thorough study of the Cochabamba-Totora route was recently completed by an American engineer; and a Government commission, headed by an Argentine engineer, was engaged on similar surveys. It is estimated that, because of the difficult nature of the country to be traversed, the construction of a Cochabamba-Santa Cruz line would cost between £8,000,000 and £10,000,000.

In spite of the great natural advantages of this region—the vast extent of level and fertile land and a highly favourable climate—agricultural development has probably fallen off 25 per cent during the past two decades. This decline is due largely to the fact that new lines of transportation have been pushed in from the outside toward the Santa Cruz country, tapping fields that were formerly markets for the consumption of the products of that region.

The Santa Cruz plains are excellently adapted to the raising of sugar cane, which is generally planted in November and cut in May, the same plants being worked for three or four years. The sugar produced is of fairly good quality, in spite of the antiquated methods used in refining it. Most of the industry is carried on by small crushing mills operated by ox power, and the sugar is whitened by means of mud.

The actual production of cotton represents only a very small proportion of the possibilities of the region in this product. Two varieties of plant are commonly grown. One of these is ready for picking in five or six months, with a fibre from 4 to 5 centimetres long. The other is a native cotton bush or tree, which grows to a height of 6 feet or more and bears for about 20 years. This plant produces from 6 to 8 pounds of cotton twice a year, and an acre will produce about three 500-pound bales of seeded cotton.

Rice is an important article of local diet, and is widely grown in the lower-lying districts of the Department. Coffee of prime quality is grown about San Jose and Santiago in Chiquitos, though in limited quantities. It is also produced in other parts of the Department.

Though formerly important in some districts, as in Vallegrande, the cultivation of tobacco has declined. Growers claim that the Government monopoly has discouraged the industry, though some tobacco is still made up into cigarettes at Vallegrande. In Chiquitos three crops of tobacco are produced from the same root.

Wheat, barley, and potatoes are grown in Vallegrande. Maize does well and is widely grown throughout the Department. A good grade of cacao is produced in the north-eastern section of the Department, and yerba maté has been successfully grown in Chiquitos and Velasco. A large variety of fruits, including bananas, oranges, pineapples, melons, lemons, alligator pears, grapes, figs, and pomegranates flourish in this part of Bolivia. Oranges and lemons grow wild, melons yield practically the entire year in Chiquitos, and excellent vegetables can be raised almost everywhere. Yuca or mandioca, especially, constitutes a very important item of diet among the common people of the region.

Stock raising is at present the most important industry of the Department. In the plain-country there are wide areas of lands covered with high grass, on which large herds of cattle feed. In the Chiquitos region herds are smaller, but the pasture lands are sufficient to accommodate a far greater number of cattle. The Beni and the northern Provinces of Argentina are the only outside markets for the cattle of Santa Cruz, and it is the limited capacity of this market which constitutes the principal obstacle to the expansion of the industry. It is impracticable to drive cattle in any considerable numbers over the mountains to Cochabamba. Large numbers of hides, however, are sent to Sucre and Cochabamba as sole leather.

The Department is excellently adapted to the raising of hogs and much of it is well suited to sheep and goats. Existing conditions are not favourable for horses and mules because of the wide prevalence of the "mal de cadera" or "peste de lomo," which attacks the spinal cord, generally with fatal results.

The basin of the Quisere River passes through the three auriferous regions of Concepcion, San Javier, and San Rafael. The placer beds of San Javier were worked during the Jesuit régime, as were also the deposits of the San Simon district in the Itenez country. The Rio San Miguel which has a quartz bed and skirts some low mountains where gold is known to occur, possesses alluvial deposits which could be worked with dredges for part of the year. Little has been done of recent years to exploit the gold resources of the three north-eastern Provinces where the metal is found. Silver is known to exist in the mountains of Colchis, in Chiquitos, and iron and quicksilver have been found in Cordillera and Vallegrande. Salt beds in the northern Chaco, to the south of San Jose de Chiquitos, are being worked at present.

The natives have long baled oil from seepages in the region. Two classes of oil are brought into Santa Cruz from two different localities about 60 miles apart, and not connected by a range of mountains. One series of seepages is located in the canyon of Espejos about 15

miles from Santa Cruz, and a few miles to the north of the Cochabamba road, and the other is located in a canyon in the mountains near Buena Vista, about 50 miles from Santa Cruz. These oils have a specific gravity of 48° Baumé, and yield about 78 per cent. of burning oils.

There are probably over 60,000 square miles of forest in the Department of Santa Cruz. Scattered over the great plain about Santa Cruz are isolated patches of woodland and in parts of Chiquitos and Cordillera there are wide expanses of scrub forest. The Monte Grande east of Santa Cruz is a vast forest wilderness, and across the northern part of the Department from Sara east across Nuflo de Chavez and Velasco to the Brazilian border there stretches an immense area of real tropical forest. These forests contain a great variety of valuable trees, among which are found mahogany, ebony, quebracho, lapacho, jacarandá, curupay, walnut, *lignum vitæ*, Spanish cedar, and the giant carob. Some of these are cabinet and construction woods; others, like quebracho and curupay, are valuable for their large tannin content. In spite of the timber wealth of the Department, lumbering operations are very limited, and saw-mills are small and few in number. Axes, adzes, and cross-cut saws are the principal tools used in lumbering.

The extraction of rubber is an important industry in the northern section of the Department; part of the product is taken out through Puerto Suarez, but most of it is exported by the Itenez and Madeira.

The production of cane alcohol is the most important manufacturing industry of the region. In 1918 there were produced in the entire Department, 352,054 litres of cane alcohol, and 79,923 litres of cane brandy. There are 241 establishments producing alcohol of which 113 are in the Province of Cercada.

There are also tanneries, saddleries, cigarette factories, ice factories, sugar refineries, and sawmills, most of which operate on a very small scale. Rubber ponchos and rubber shoes are made in Velasco and Nuflo de Chavez, but the industry is of little importance.

A condition of general depression and stagnation in business exists in the Santa Cruz country, and there can be little hope of any radical improvement until that region has better connections with the outside world. Only the building of railways from either direction can give it the prosperity to which its natural possibilities entitle it.

The principal goods in demand are cottons, canned goods, general hardware, such as axes, saws, and cane knives, carpenters' tools, hats, and general wearing apparel of a cheap grade; prepared medicines, tin and galvanized wares, rifles, light ploughs, and gunsmiths' and machinists' tools. There is also a need for small sugar-making apparatus, mills for husking rice, and light sawmill equipment. It should

be remembered that all machinery sent into the Santa Cruz country must be transported from river or railhead to its destination by means of oxcarts, and that, moreover, such merchandise cannot be transported over the Cochabamba route, which is used only by mules.

CORRESPONDENCE.

SURFACE COMBUSTION

I spoke from "information received," and am glad to know wrongly; but I am not sorry that I did so, as Professor Bone, in consequence, has the opportunity to make known that his remarkable burner has even been improved and that its use is being developed. I assume a separate supply of air under pressure is still indispensable. If the burner can be at all generally applied, it may be the salvation of the kitchen and make possible the return to rational healthy cooking by radiant heat. I should like once more to realise a fond memory of my youth --to enjoy the creamy mellowness of the Yorkshire pudding begun in the oven, but finished before the fire and anointed with the juices and flavours from the Jack-turned, roasting—not baking—joint above. Prof. Bone has made a great beginning. I would urge him to leave Royal Society academic research to others and apply his inventive powers to the development of an efficient rational system of household cooking by gas. We are making no proper use of our "science" to-day.

HENRY E. ARMSTRONG.

GENERAL NOTES.

ROOFING-TILES IN EAST AFRICA.—The provision of roofing material for buildings in the tropics is often a matter of difficulty. Corrugated iron is largely employed, but it is frequently very costly, and, moreover, tends to make the building unbearably hot. In several countries in Africa it has been suggested that roofing tiles should be made locally, and search has been made for suitable materials. Specimens of clay and sand, collected in Uganda, and of clay and diatomite from Kenya Colony, have recently been examined at the Imperial Institute in order to ascertain their possibilities in this direction, and the results of the investigation are given in the current number of the Bulletin of the Imperial Institute. It is shown that tiles of good quality can be made with a suitable mixture of the clays and sand from Uganda, whilst good tiles can also be made from mixtures of the washed clays with "grog," i.e., clay which has been burnt and finely ground. The clays from Kenya Colony were also found to be suitable for making roofing tiles. The results obtained with the infusorial

earth or diatomite (which contained a certain proportion of clay) are of special interest, as this material, which does not appear to have been employed previously for the purpose, furnished tiles which were much lighter than ordinary roofing tiles, which is a great advantage. There are extensive deposits of infusorial earth in Kenya, not at present worked.

DAVID HUGHES'S WIRELESS TELEGRAPHY APPARATUS—In a letter published in the *Times* of March 28th, Mr A. A. Campbell Swinton, F.R.S., writes:—A search, suggested by myself to Colonel H. G. Lyons, of the Science Museum, made amongst the contents of a room full of Hughes's personal effects that for the last 20 years have been stored in a furniture repository in London, has revealed the existence of a number of electrical instruments, comprising the original first microphones invented by Hughes, and the actual apparatus with which he made his early wireless experiments, all obviously constructed with his own hands. The several instruments can easily be identified by the illustrated descriptions in the notebooks, and we thus have a collection of great historical and scientific interest, which, through the generosity of the Hughes trustees, has been presented to the Science Museum in South Kensington, where it will shortly be on public view.*

INSTITUTE OF TRANSPORT—The Council of the Institute of Transport announces that it will undertake suitably to celebrate principal events in transport history, and, in this connection, will arrange for celebrations of the centenaries of the opening of the Stockton and Darlington Railway in 1825, and of the Locomotive Trials at Rainhill in 1829, at which latter the famous engine "Rocket," by George Stephenson, established the supremacy of steam engines over the then known method of steam transport, namely, stationary steam engines. These celebrations will probably be held in connection with the annual Congresses of the Institute in the years in question, and a centre in the vicinity of Stockton and Darlington and of Rainhill will be selected for the purpose and appropriate methods devised for adequately celebrating these important events.

INDIAN LAC, TURPENTINE AND ROSIN—About 94 per cent of the world's supplies of lac (shellac, etc.) comes from India, the rest from Indo-China and Siam. In spite of this practical monopoly of the trade, the state of the industry in India is not altogether satisfactory. The Special Committee on Gums, Resins, and Essential Oils, of which Sir Harvey Adamson, K.C.S.I., was Chairman,* make various recommendations for improving the present con-

ditions of the industry, for placing the manufacture on a thoroughly efficient basis, and safeguarding the interests of India and the Empire. Although India possesses large areas of pine forests from which turpentine and rosin could be obtained, the country has not hitherto figured among the large producers of these materials, and is still dependent to some extent on foreign countries for its own requirements. The Special Committee consider that every effort should be made to increase the Indian output, and recommendations are made with this end in view. The last section of the publication gives interesting particulars relating to the production of turpentine oil and rosin in India, and the characters of the products obtained from the different Indian pines.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.

- MONDAY, APRIL 10.** Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. Oldham. "Hints on the Storage of Perishable Produce with Special Reference to Eggs." Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Mr. F. Roberts, "Seven Decisive and Suggestive Scenes in the History of the Secular Contest between Conscience and Power." Surveyors' Institution, 12, Great George Street, S.W., 8 p.m.
- TUESDAY, APRIL 11.** Petroleum Technologists Institution, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. A. Millar. "Galicia and its Petroleum Industry." Rubber Industry, Institute of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m. Sir Edgar Walton, "Resources and Advantages of South Africa as a Field for Industrial Development." British Decorators, Institute of, Painters' Hall, Little Trinity Lane, E.C., 3 p.m. Annual General Meeting. Historical Society, 22, Russell Square, W.C., 5 p.m. Mr. C. Johnson, "The System of Account of the Wardrobe in the Reign of Edward I." Sanitary Institute, 90, Buckingham Palace Road, S.W., 5.30 p.m. Sir Henry Tanner, "Economy in Sanitary Appliances and Methods of Drainage." Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. (1) Captain T. A. Joyce, "The Paquecha of Ancient Peru." (2) Miss A. C. Breton, "Notes on some Peruvian Antiquities."
- WEDNESDAY, APRIL 12.** Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. (1) Mr. F. W. Edwards, "Oligocene Mosquitoes in the British Museum with a Summary of our present Knowledge concerning Fossil Culicidae." (2) Prof. A. C. Seward, "On a Collection of Carboniferous Plants from Peru." (3) Miss M. E. J. Chandler, "The Geological History of the Genus *Striatotes*: an Account of the Evolutionary Changes which have occurred within the Genus during the Tertiary and Quaternary Eras." Astronomical Society, Burlington House, Piccadilly, W., 5 p.m. Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5.15 p.m. Professorial Lecture. Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. Mr. A. F. Evans, "Marine Engine Design as affected by Lifeboat Conditions."
- THURSDAY, APRIL 13.** Optical Society, at the Imperial College of Science and Technology, South Kensington, S.W., 7.30 p.m.

*The Report of the Committee, a new volume in the series of Reports of the Indian Trade Enquiry conducted at the Imperial Institute, has just been published by Mr. John Murray.

Journal of the Royal Society of Arts.

No. 3.621

VOL. LXX.

FRIDAY, APRIL 14, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

NINETEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 5th, 1922; LORD HEADLEY, M.Inst.C.E.I., in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Dawson, Frederick Lawrence, Pyapon, Burma.
Risdon, Philip James, London and Hove, Sussex.

The following candidates were balloted for and duly elected Fellows of the Society:—

Jackson, Miss Frances Agnes, Camberley.
Pe, Maung Hla, M.L.C., Rangoon, Burma.
Sarkar, M. K., Calcutta, India.
Smith, D. Curle, M.I.E.E., Kalgoorlie, W. Australia.

A paper on "Coast Erosion and its Prevention" was read by Professor Ernest R. Matthews, Assoc. M.Inst.C.E., F.R.S.E., F.G.S.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING

WEDNESDAY, MARCH 8th, 1922.

MR. JOHN MURRAY, M.P., in the chair.

THE CHAIRMAN, in calling on the lecturer to read his paper, said the subject with which it dealt had been much before the public of late, and especially during the last two years. The history of trade unionism was not a long one, but the unions were of great extent and very great power at the present time. It was perhaps natural that, their growth having been so rapid and their power having become so great, the true theory of trade unions had not yet been arrived at. It seemed to him that the leaders and managers of trade unions, the public at large, and even the House of Commons, should widen

and enrich their knowledge of trade unions, and, by so doing, put the unions—he was not speaking disrespectfully—in their place; a moral, constitutional, industrial, legal and practical place. That had not yet been done, but it was a duty for which the lecturer had very special qualifications, as was evident from the long years he had spent in the service of trade unionism and by his conduct in those years of difficulty and danger which had followed the outbreak of the war.

The paper read was:—

THE PROPER FUNCTIONS OF TRADE UNIONS.

By W. A. APPLETON, C.B.E.

A hundred years ago it would have been easier than it is to-day to secure comparative unanimity concerning the proper functions of trade unions. Then, the organisers of the movement had definite, if limited, views, and they were careful to emphasise their attitude towards religion, towards politics and towards the State. In these matters the early part of the 19th century appears to have exhibited a wider tolerance than does the corresponding part of the 20th century.

The workmen in those days were not less religious than their fellows of to-day, and if recollections of one's grandfathers and their contemporaries are of any account, they were not less keen nor less well informed in politics. Their opportunities for reading were less extensive but they appear to have discussed affairs quite as thoroughly, and to have understood them quite as fully as their grandsons. They tried, amongst other things, to keep both religion and politics out of the trade unions they were forming and developing.

It has been said that, having no votes, abstention from class politics can hardly be counted to them for righteousness. Such a contention is neither fair nor accurate.

It would, indeed, be just as fair and just as accurate to argue that because they sought to exclude religious controversies from their branches they were all unbelievers. Perhaps it would be more in harmony with historical data to say that they appreciated the impossibility of developing industrial unity, if, within their organisations, they regularised the discussion of such disintegrating factors as religion and politics.

To-day things are different. The unions are constantly and vehemently invited, at what are alleged to be reputable and representative conferences, to use their industrial power and to jeopardise their industrial interests in the furtherance of such widely differing subjects as the concession of Home Rule to India and the maintenance of despotism in Russia.

The pioneers of trade unionism found themselves opposed to problems as great as, if not greater than, those which face the men who to-day are trying to salvage the movement. They very wisely avoided undue handicaps because their tasks were already onerous enough. They were faced with extraordinary changes in the methods of production and extraordinary aversions on the part of manufacturers to any assumption of responsibility for the physical and social welfare of the men and women whose status the altered methods endangered. Mechanical power was overshadowing man power; the factory was taking the place of the workshop; the free craftsman, owning his own tools, purchasing his raw materials, and selling his products directly to the consumer, was becoming more and more an attendant upon power-driven machinery, and the servant of men who owned the machines. New industrial relationships were being created, and with them the necessity for new methods of protecting from undue exploitation the workman whose willing skill and capacity enabled him to meet the requirements of the industrial overlords.

It was no use arguing the desirability, or the undesirability, of these changes from individual to collective production. They were there, and the inevitability of their development was obvious. Human nature being what it was in the days of Cain and Abel, and what it is to-day, it became necessary to restore some equilibrium by the provision of machinery for securing the recognition of industrial rights,

the highest possible payment for industrial services, and the enforcement of collective, as against individual, bargaining. These were then assumed to be the proper functions of the original trade unions.

They proposed to give effect to these functions by negotiation and mutual agreement between the interests involved where this was permissible or possible. Failing this kind of arrangement, they were prepared to embark upon industrial warfare and to force what they considered to be their just demands by withdrawals of labour. At one time it was most common to withdraw only the labour involved. Then it became the practice to withdraw related labour, that is, men in the same employment, or the same industry, and, latterly, there has been the demand, and the attempt, to paralyse, not only industries concerned, but all industries. The first withdrawal of labour affects only the firm or firms actually and directly in dispute; the second involves, irrespective of location or association with the causes of dispute, all the firms in the industry; while the third involves the whole community. In any case, there is suffering and loss, but when the latter form of withdrawal is attempted, loss develops into disaster.

The strike against the bad employer invites and secures public sympathy. A strike against the good employer, for the purpose of coercing the bad one, may be condoned on the ground of tactics; but a strike which embroils all industries and all public services involves all in misery, and is condemned by all except the fanatics who propose it, or the scamps who hope to profit by it.

Elsewhere I have described a trade union as an organisation for the betterment of wages, hours and working conditions of persons engaged on similar materials, using similar tools, and producing similar results, and I should say that to-day their proper functions embraced every problem connected with, or arising out of, employment and unemployment, and out of trade and commerce, in so far as these affect employment.

Amongst these problems would be those affecting wages, hours, conditions under which employment is provided, safe-guards against industrial disease and accident, compensation where disease or accident results, and provision against unemployment. I should consider the unions were

justified in using their power through any of the political parties, to remove, or to prevent, the imposition of restrictions that hampered manufacture or commerce, and, by so doing, developed unemployment.

Knowing something of trade union opinion and practice, I should not include amongst functions which they can satisfactorily perform, those which cover the provision of capital, the discovery and exploitation of markets or the actual direction of business.

If work is intelligible effort intelligently applied then wages may be described as the reward of those who create value by work. In discussing the problem of wages, it is desirable to start by recognising that work, qua work, has not sufficient value to justify claims for wages. It may provide the exercise necessary to the maintenance of health, but it has no more moral nor financial value than the treadmill.

There is much foolishness talked about the provision of work, particularly the State provision of what is termed "useful" work. In a country dependent, as is Britain, upon outside sources for much of her raw material and for three-fourths of her food, the only useful work is that which produces commodities, or provides services, which can be exchanged in overseas markets for raw materials and food. Repairing roads, reclaiming foreshores, and planting forests is work which has disciplinary and internal value, but it only affects the external purchasing power of the country to a very limited extent.

Whatever value is thus created, accrues slowly and benefits future generations more than existing ones.

In proposing work of this kind it is always advisable to consider carefully the national circumstances at the time when the necessary capital expenditure is demanded, together with the period which must elapse before reasonable returns can be expected. Unless this is done the general circumstances may be made worse instead of better. It would, indeed, be foolish to spend money on forests, which for many years can give no exchangeable value, when the money is needed for machines and commodities which promise an immediate and a recurring return.

In describing wages as the reward of those who create value by work, the trade unionist is not likely to overlook the fact that the reward is sometimes inadequate, nor do I personally make the mistake of

assuming that monetary return represents the whole of the reward. Every workman who has the instincts of the artist, and there are hundreds of thousands of such, knows that there is an important form of return which finds expression in the personal satisfaction and happiness which accompanies the sense of work well done and things created.

The thoughtful trade unionist will differentiate also between nominal and actual wages, between money received and purchasing power conferred, between the unit of measurement and the useable and consumable things for which this unit can be exchanged. These latter things are indeed the real wages. All other things—gold, notes or cheques are just representatives.

The right to discuss a subject involves the duty of trying to understand it, and no conscientious trade unionist should attempt to negotiate wages questions without having tried to understand the factors that govern wages. Opinions will, necessarily, differ as to which are the most important factors. Personally, I should place them in the following order:—

(1) Those involving the workman's capacity, such as physique and general health; knowledge of tools and processes; period of training for specific work; measure of intelligence and good-will.

(2) Those affecting the personality of the manufacturer, in which I should include general knowledge, industrial and commercial experience, initiative, adaptability, enterprise, courage and the ownership or possession of capital.

(3) The accessibility and cost of necessary raw materials.

(4) The accessibility of markets, together with the transport facilities and costs.

(5) The amenability of markets, particularly overseas markets, to the conditions governing production at its centre. This would include questions relating to the nature of the commodities required, their quality, the price likely to be obtained, and the profit likely to be earned.

(6) The inviolability or otherwise of contracts of service entered into between workmen and employers, particularly where the observances of these contracts affect continuity of production and certainty of delivery. In this connection it is important to weigh the effect of the necessity for inserting clauses safeguarding the manu-

facturer, or the contractor against losses arising out of sudden strikes. It is obvious that countries inserting these clauses incur very serious handicap as against countries where they are unknown or not observable. Such reservations indicate a liability which may not mature, but which always threatens and which frightens prospective customers.

(7) The facilities which exist for the fullest use of fixed capital, such as buildings, machinery, railways, docks and ships.

(8) Extraneous factors such as taxes and rates. As these must be charged to productive costs, their weight and their incidence demand the gravest consideration.

(9) Political interferences which limit the use of fixed capital, or check enterprise, and by so doing, increase costs of production or distribution. A good example of this kind of interference is the legislation which permits the pork butcher to sell cooked chops after seven o'clock in the evening, but which fines him for selling uncooked ones during the same hours. The absurdity of such legislation is obvious, but no party in Parliament has made effective efforts to repeal it.

In addition to the factors which govern the rise and fall of money wages, the trade unionist is justified in defining his attitude towards those which reduce real wages. Amongst these, he will find none more pernicious than the subsidies which have been given to munition workers, to building, to railways and to mines. Perhaps nothing in recent years has so appeared to humiliate Parliament as the spectacle of one Party foolishly demanding subsidies, and another Party weakly conceding them. These subsidies, by creating artificial purchasing power without providing contemporaneous and equivalent production of commodities, have increased prices enormously, and to the extent of this increase they have seriously penalised less fortunate sections of the community.

It is common amongst some who have attached themselves to the trade union movement to declaim against what they are pleased to call the moral degradation of receiving wages. I have been a wage earner all my life and can honestly declare that I have never felt this degradation. Wages, whether they are paid in cash under capitalism, or in kind, under socialism, carry neither moral nor social stigma, except to those who haven't tried to earn them.

After wages, the trade unions are justified

in pressing their right to intervene where hours of employment are too long. The forty-eight hour week has been their ideal, and they regard its maintenance as a cardinal matter of policy. There are, however, occupations in which eight hours would not only be excessive, but impossible. On the other hand, it is argued that there may be occupations so little exhaustive of mental or physical fibre that eight hours appear, by comparison, too little.

Under socialism, if its protagonists are rightly understood, attempts might be made to secure uniformity of effort but not uniformity in period of time over which the effort should be spread. I have always understood that "from each according to his capacities" does not necessarily signify from each according to the time occupied. I admit the difficulty of meeting the assertion that there is no fairness in the demand that a locomotive engine driver, or a signalman in a busy junction box, shall work the same hours as the porter in the wayside station whose most exhaustive work is that of waiting for the trains that seldom come.

There are indoor and outdoor occupations, and in the former the unions should have no difficulty in realising their ideals. Most of the latter, however, are governed by the elements. In these outdoor occupations, effort must, of necessity, wait upon opportunity. Tides must be taken at the flood, and hay gathered while the sun shines.

In demanding the right to exercise their functions, the trade unions must of necessity display their capacity for apprehending the extent to which their demands are possible of realisation, and the point at which reaction becomes inevitable.

Inside the unions there are indeed many who understand the danger of a high minimum wage, and a low universal maximum period for work. They fear that the advocacy of extremes may penalise almost equally, though differently, the skilled and the slow. For the former there may be inadequate remuneration, and for the latter inadequate employment. If it is necessary to fit the punishment to the crime, it is necessary also to fit the reward to the effort.

The conditions under which employment shall be provided or undertaken divide themselves into those which belong wholly to the union and those which may, without serious disadvantage, be undertaken by the State. In the former are included methods

of production, and in the latter questions of industrial hygiene and common law. The unions might, with some show of justification, claim the right to intervene in both, but, whereas their claim in respect of workshop hygiene and common law might be questioned, in method it is indisputable. The conditions under which work shall be performed; what shall be the day or the piece rates; how the men shall be apportioned to machines, or in gangs; the size of the task where the task method is employed; the times at which work shall begin and cease; all are questions which the trade union may fairly claim to discuss with the employer. But where sanitation, cleanliness and deliberate theft, such as time cribbing, or such theft as may arise from payments in kind, are concerned, the State can most easily secure that uniformity which makes for health amongst workpeople, and equality of opportunity as between employers.

After wages, hours and working conditions, there is no subject so interesting to workmen and to trade unions as compensations for accidents arising out of, or in connection with, employment. To the accident proper has now been added industrial disease, and no trade union considers itself up-to-date unless it provides special, and if needs be, legal assistance in cases of accident or industrial disease. These cases afford one of the few opportunities the trade union official has of going into court, on equal terms with the lawyer. As a rule, some official of the unions specialises on this subject, and where questions of fact only are considered, he is often a more successful advocate than the lawyer. Even where questions of law are involved, he is sometimes, owing to specialisation, able to do all that is necessary.

The value of the trade unions performing this particular function must have been obvious, or Parliament would not have conceded so much of legal procedure to them. It was generally known that workmen, left to themselves, often failed, either through fear or ignorance, to notify accidents within specified times or in the manner necessary to ensure payment of the compensation to which they were entitled. When it became not only possible, but customary, to claim through the union, fear became less common, while ignorance was assisted.

Early in their existence the trade unions realised that wages were affected, if not altogether regulated, by the laws of supply and demand. If the supply of labour was

greater than the demand, the market value of labour depreciated. They were not able to control demand, but they saw some possibility of regulating supply. If, in bad times, the unions could hold back what was surplus to requirements, they might maintain wage rates and working conditions exacted during times that were favourable. They could only hope, however, to hold back this surplus of labour if they could offer it subsistence.

The wiser organisations, recognising this, added various forms of unemployment benefit to their objects, and in doing so, did more than restrain surplus labour,—they went far to disarm the hostility of women. These, poor things, carried and their sisters continue to carry, the major portion of unemployment's burdens. Upon their shoulders rests much of the responsibility for the maintenance of the home. They knew from experience that hostility to the interests or the apparent interests of the employer, or to their unrestricted authority over their employees, brought punishments, which might include dismissal and boycott. Because they knew this, and preferred reduced standards of living to no standards, their influence was usually against their men's association with organisations formed for the definite purpose of waging war upon employers, whose ability to punish approached the absolute. The women were not satisfied with the conditions obtaining, but they were afraid. The provision of unemployment benefit reduced their fears and helped to bring them on to the side of the unions.

The assumption by the unions of the whole of the burden of unemployment relief was inevitable. They had in those days no possibility of help from elsewhere. Their existence was resented; they were regarded, and described in law, as organisations in restraint of trade, when it would have been wiser and truer to have described them as organisations in restraint of unscrupulous traders. I have often felt that this error in description emphasised bitternesses, developed industrial unrest, and sequentially cost the country hundreds of millions in disputes that were preventable had better relationships existed.

The employers, in those days, gave little encouragement to social aspirations or cultural tendencies. Then, as now, many failed to see the wisdom, or the economy, of taking a hand and bearing a share in

unemployment costs. Instead of collectively helping in times of stress, they too often rejoiced when funds failed, because an empty trade union exchequer meant ineffective trade union opposition to what was regarded as the employer's right to control his own business. By this was frequently meant the right to depress at will, and even apart from the suggestion of commercial necessity, the wages and the working conditions of their employees.

In face of the fact that the Israelites crossed the Red Sea because of the unrest obtaining in Egypt, it would be absurd to charge the British employer with all the responsibility for its existence. But there is no escaping the conclusion that in the days of industrial transition he did little to obviate this unrest, or to encourage that mutual understanding between capital and labour, without which neither can be even reasonably successful.

The mental conception of industrial economies which led the unions themselves to undertake the provision of unemployment benefit continued to operate until the advent of what was known as the new unionism. Then, for many people, the outlook changed. The conception of numbers and the power of numbers grew, and faith in the political solution of economic problems was revived. To secure numbers, it was necessary to reduce contributions, and unemployment benefit, being after strike benefit the most expensive, and involving the greatest actuarial uncertainties, was jettisoned in order to meet the demand for cheapness. In some of these newer organisations the contributions were so low that continued existence would have been very difficult had it not been that an appreciable portion of the membership was of the "in and out" variety and seldom became entitled to all the benefits set forth in the rule books.

It is significant, and flattering to the older generations, that these unions with new policies, while eliminating the responsibility for providing funds for unemployment, consistently insisted upon their right to administer the benefit, even when the funds were provided by the State. It is less than two years since the Parliamentary Committee of the Trades Union Congress placed an embargo on trade union association with unemployment administration if Friendly Societies were allowed to participate. This embargo has

not, even yet, so far as my knowledge goes, been officially and publicly withdrawn. The point of view was emphasised by the General Federation of Trade Unions, which sent delegates personally to press the claims of trade unionists upon the Ministry of Labour. Their action was not prompted by hostility to the Friendly Societies, but by fear for themselves. They realised the danger that would threaten trade unions if surplus labour received its subsistence through other media.

The Government accepted the contentions put forth on behalf of the trade unionists. Personally, I think the Government had no option. The unions had established at least a squatter's right. They had been first on the pitch, and during a hundred years had spent many millions of pounds on unemployment. Where employers had shown any desire to collaborate, they had also, actuated alike by considerations of mercy and self-interest, set up forms of machinery for returning their members to employment. The Act of 1920 gave them large powers and small financial responsibilities. The men of 1820, the pioneers of trade unionism, were faced with almost similar circumstances. Had they been given similar opportunities, they would, I believe, have made infinitely better use of them than did their present-day successors.

The failure to exploit successfully the 1920 Act arose from rampant competition between the unions, actuarial ignorance within the unions, and within the Government, and the belief, which was almost as common as it was baseless, that new standards of living could be achieved by enlarging the powers of bureaucracy or by changing forms of government.

Common consent has given Mr. Lloyd George the honour of first voicing the possibility of receiving ninepence for fourpence, but he was neither the first nor the last to convey the impression that he was putting such a possibility into practice. He had eloquent predecessors, and he has equally voluble successors. Anyone reading the leaflets issued by some of the trade unions during the controversies which immediately preceded and succeeded the passing of the Act of 1920 will find ninepence for fourpence transcended by a pound for sixpence. Whatever calculations these unions made must have been based upon limited experiences with small benefits, and during a period when memberships

were increasing much more rapidly than liabilities were maturing. Their calculations were undoubtedly affected by the errors of the Departmental actuaries, who assumed that the average weeks of unemployment would be two-and-a-half, and seeing these figures, unions possessing hundreds of thousands of members joyously proclaimed their willingness to pay a pound per week for a sixpenny contribution.

How the officials of these unions expected to pay fifty shillings, plus costs of administration, out of twenty-six shillings, not even the Delphic Oracle could say. They never attempted to say. They carried on for a few months until bankruptcy overtook them, and then they suspended benefit. Some of the circulars announcing these suspensions and renunciation of future effort are pitiful admissions of ineptitude. All the excuses put forward in extenuation are feeble. There are usually not more than two general ones. They had to make grandiloquent promises in order to out-promise the competing unions, and they regarded the Government's estimates as providing wide margins of safety.

While folly and incompetency existed, it is comforting to realise that it was not universal. Some of the unions, and amongst them some of the semi-skilled and unskilled ones, kept their heads, and in spite of the competitive threats formed their schemes so as to keep them solvent. Recently, from conversation with Mr. J. N. Bell, the Secretary of the National Amalgamated Union of Labour, I gathered that this Union had a scheme which had, so far, weathered the storm and that he was optimistic concerning its future.

Incidentally, I may say that the General Federation of Trade Unions prepared a scheme when trade unions seemed to anticipate opportunities of usefully administering the Act. It rejected the official estimates of two and a half weeks, and based its calculations on five. It was the opinion of the Committee that post-war circumstances would involve at least this amount of unemployment. When it became the obvious intention of unions and the Government to let things rip, the Committee refused to join in dangerous competition, and wisely put its scheme in the waste paper basket.

All this may be said only to weaken the claim of the unions to deal with unemployment insurance. It would, if all the failures

were failures of normal times, and were wholly chargeable to the unions. But the period of this great experiment was not normal. Mentally and physically, there has been great national impoverishment. The war involved the best of the people in the highest percentage of mortality. The numbers of those whose idealism finds expression in the greatest devotion to duty, and the greatest willingness to sacrifice, have been grievously reduced. Admittedly, the trade unionists, together with other people, ran after economic heresies, but experience is driving them to renounce these, and I still feel justified in insisting upon their right to deal with unemployment.

It is open to anyone to recall my own contention that the right to administer unemployment involves the duty of trying to understand the causes. I agree, and for years I have, in writing and in speaking, pleaded for the non-partizan study of the subject. I am not the only one. Others before my time have pressed this point of understanding. More than a hundred years ago the House of Commons discussed the subject, and then there was the same haziness concerning causes, the same ill-considered rush for palliatives and the same incentive to pauperism.

As far as one may judge, the only difference was one of attributed cause and degree. They had to deal with sixteen millions; we have to deal with forty-eight. They argued that it was due to the deficient harvest. Our socialists and communists argue that it is due to capitalism, and the Prime Minister has declared it was due to the war. Charles James Fox, while admitting that war was responsible for some of the trouble, exclaimed: "But, if there are other circumstances which have operated along with those arising out of the war—if the evil has proceeded from many and complicated causes—nothing can be more mischievous than to ascribe it solely to one cause, and to proceed as if that were the fact."

Error is not the prerogative of the trade unions. Others with wider experience and better opportunities have erred in exactly the same way, and it may safely be assumed that error, and the consequences of error, will continue until the men who are most desperately concerned have placed more definitely upon them the responsibility of studying and mitigating this life-destroying problem.

Many who regard the right to treat this function as next in importance to the functions relating to strikes, recognise the difficulty of securing by voluntary means the necessary contribution. The workman is not much better as an economist than is the Government. Perhaps the outstanding difference between them is that the former wants a lot for nothing, while the latter gives a lot for nothing. Some form of compulsion appears to be inevitable, and if compulsion is applied, it should be by those most directly concerned, that is, those who live by the industry. And by those who live by the industry is meant those who live by wages, and also those who live by profits.

In the scheme put forward recently by the General Federation of Trade Unions, it is suggested that each industry shall provide and administer its own unemployment fund; that the industry, rather than the union, shall be the unit, and that contributions shall consist of a percentage on wages.

Personally, I care little whether the workman or the employer is the one who actually pays the contribution. In any case, it will come out of the industry, but for the sake of simplicity and economy in connection with administration, it seems preferable that the employer should be the actual payer.

It will be objected that industry cannot bear this charge and that a residuum of unemployed would be left outside the industries' schemes. I should give the same answer to the first objection as I gave to the Manchester Chamber of Commerce, viz., that the industries were already bearing the cost, plus the cost of bureaucratic administration and that of moral deterioration.

For the workers who cannot be grouped in specific industries there is always the possibility of a common society. Such a society, by reason of the diversity of its risks, might more than hold its own. There remains, of course, the residuum which would include unemployable, as well as some other unfortunates.

Expressing entirely my own personal opinion and realising that what I say may be both misunderstood and perverted, I cannot see anybody better fitted to deal with these cases than the Boards of Guardians. The Guardians are like the dogs with the bad names, and their early-Victorian records do

not suggest that they then overflowed with the milk of human kindness. But they are popularly elected bodies, and as such, are much more amenable to enlightened public opinion than is appointed bureaucracy.

In any case, I cannot see how a country impoverished as is Britain can afford the luxury of several government departments to deal with what is, after all, one problem: the problem of maintaining life when life is jeopardised by unemployment arising out of industrial stagnation, physical incapacity, or culpable idleness.

Such schemes will be fought by those who aim at perpetuating the antagonisms between capital and labour, but this form of co-operation would do more to perpetuate industrial peace and to stabilise industrial enterprise than any other conceivable effort. Such schemes offer the employers a chance of demonstrating their interest in those who work, and they offer the trade unionist and the willing worker a chance of separating themselves from those who only work under compulsion.

Perhaps one ought to apologise for devoting so much time to this particular function. But it is the function of the moment and unless something is done, and done quickly, neither trade unions nor national existence can continue.

The question will certainly be asked—ought trade unions to claim political, as well as economic and benevolent functions? I have in a sense anticipated this question by stating that, in my opinion, they are justified in using their votes and their influence in favour of any party that can help them, or against any party that is hostile to them. Where I join issue with many is against the demand that they should forfeit their autonomy and jeopardise their industrial interests and create dissension amongst their members by tying themselves, for all time, to any one political party, or to any one form of religious thought.

I never claim altruism for the trade union movement. Its business is to look after the wages, the hours, and the working conditions of its members. It has no real obligations to those who are not members. Their remedies, if remedies are needed, lie elsewhere. I have been asked whether a trade unionist ought not to use his political as well as his trade union arm, and my answer is an unequivocal yes. But he should, in developing the political arm

see that the trade union arm is neither tied up, nor broken, nor withered. He should also be careful to see that it is not used to cut out his own stomach.

The political propaganda which preceded and culminated in the Miners' dispute paralysed that great industry and nearly paralysed the State. The miners suffered for their attempt to achieve a political result by industrial action, and they are suffering to-day; but there are other industries who suffered more, and who will suffer longer. Strikes and threats of strikes to achieve political ends, by retarding normal recoveries, have done almost as much to accentuate misery as did the war.

It must always be so. The objectives and the responsibility of the trade unionist and the politician differ. The latter has no aftermath that need trouble him. He can, and he often does, cynically ignore that part of his propaganda which turns out to be unprofitable. The trade unionist is differently situated. He must face the facts of failure, and if he has any heart, it will be lacerated by the results of failure.

Having passed through many strike experiences, I would limit their number by eliminating the political one. I would also eliminate the political control of the unions' activities.

Perhaps the only time I should consider an industrial strike in furtherance of a political objective justifiable, would be if the need arose to strike against an attempt on the part of politicians to limit the right to strike.

My friend, Mr. Archie Crawford, Secretary of the South African Federation of Trade Unions—at one time deported from South Africa because of his trade union activities, has recently declared that the economic law is inexorable. He is right. However opprobriously we may speak of the operation of economic law, we cannot escape the fact that it is inexorable, and that it is folly to accentuate its burdens by the assumption of responsibilities that arise from following political objectives.

The trade unions cannot, with or without political alliances, resist the operation of economic law, but they can, by the perfection of their organisation, and the creation of necessary financial reserves, prevent, or at least, oppose attempts to add to the pressure of this law by expressions of human selfishness.

They can, and should, fight the employer who seeks to transfer all the losses arising from his incapacity or lack of foresight to the shoulders of his workpeople. They are justified in condemning and fighting the employer who seeks to perpetuate a ten per cent. dividend plus payments of income tax, plus liquidation of share liability, plus share inflation, at the expense of the permanent stability of the business and at the risk of creating unemployment amongst the people who have made such dividends and arrangements possible.

In conclusion, I desire to reiterate my earlier contention that trade unions are entitled to claim as their rightful functions all those problems which deal with employment and unemployment.

DISCUSSION

THE CHAIRMAN (Mr. John Murray, M.P.), in opening the discussion, said the meeting had had the advantage of listening to a brilliant paper, packed with knowledge and information, and the result of those qualities, wisdom and sense.

Before commenting on it, however, he desired to read an extract from a letter from Sir Alfred Yarrow, who was unable to be present:—

"In connection with what we may call 'Labour questions' I should like to point out a matter which appears to me not to have had sufficient importance attached to it.

"It has been generally received that wages should rise with the cost of living; under normal conditions that is quite correct, but I think it must be admitted that every section of the community should pay something towards the expenses of having been freed from the German peril.

"Some have lost their lives, some have lost their limbs, capitalists have lost money, and, if those who work for wages have their wages increased to correspond to the increased cost of living they will not have paid anything towards the expense of the war, which they certainly ought to have done. Therefore wages to rise in proportion to the cost of living without allowance being made for the workers' share in the cost of securing their safety at home is, on the face of it, unjust to those who have suffered."

Personally, he agreed with Mr. Appleton that trade unions should not attach themselves to any one political party, but should use all. Neither politics nor the trade unions had anything to gain from the close union of trade unions with any political party. The author also said that the standard of living could not be raised, maintained or prevented from falling by a bureaucracy, and that was profoundly true, although many millions of people in this

country did not believe it, but argued superficially, from their experience during the war, that with the right people in the Ministry of Labour and the House of Commons wages could be maintained—disregarding the inexorable economic laws to which the lecturer had referred.

He agreed with the lecturer that the provision of "useful" work in times of unemployment was only of value in so far as it served to keep the peace at home; it was only by the re-establishment of foreign trade that any real good could be done. He agreed also with what the author said about subsidies. People were always shouting "Give, give, give," and wanting grants, doles and contributions for all manner of purposes; but when, in order to find the money required, the Government imposed taxation, those same people were loud in their complaints. It was necessary to exercise common sense and give up the incessant clamour for Government help and grants, which could only be provided out of taxation.

The lecturer said he did not wish politicians to toy with the idea of limiting the right to strike. Politicians had a greater sense of self-preservation than to wish to do so. The further remark in the paper, that the right to discuss a subject implied the duty of trying to understand it, was so straight and true as to be almost offensive. The state of most men and women towards economics was a state of either first thoughts or second thoughts. The first thoughts consisted of all those follies and fallacies which people, looking at the phenomena of work and money and exchange, imbibed at once and believed to be true. Then came the economist, whose aim it was to replace those first thoughts by second thoughts. The wage-earning population was dominated by its first thoughts, and had a very weak sense of the continuity of causes and effects. The lecturer talked of action and reaction, and throughout his paper implied that the world was a system, and as such could not be interfered with without some difference being produced and without the working of it being affected. The wage-earners as a class had not had sufficient education to appreciate that; they thought there could be a break between cause and effect, and that if one only did a thing once or did it furtively nothing would happen. The working classes had two great misconceptions. They believed that the rich were not really subject to inexorable laws and influences but were, as it were, shock absorbers. If seven workmen indulged in "Ca' Canny," so that an eighth man and a boy had to be employed, the eight of them saw a certain resentment in the office, and imagined that was the only result produced. They did not appreciate the fact that the people in the office had to take steps to meet the altered situation by raising the price of their commodity. That meant that customers bought less, and therefore the whole-

saler ordered less from the manufacturer, who then dismissed the eighth man and the boy.

To take another point, there was a great sentimental outcry in favour of a tax-free breakfast table. The money had to be found in some way, however: a tax-free breakfast table merely meant that some other table had to be taxed; but millions of people could not be made to see that. In the case of income tax, the poor man said: "I am poor; don't tax me; go for the rich." He thought the rich man would grumble, but that would be all. But as a matter of fact, if the rich man was an employer, the result would be that he would employ less; if just a saver, who put money in the bank which was used for trade, he would save less, and so employment would be reduced all round. In short, the system of organised work within a nation and interchange among nations was a system which kicked back; if one interfered with it at one point, one could not be sure the result would not be felt at ten others. He did not know how that was to be brought home to the wage-earning class except by years and years of educational effort.

He did not altogether agree with the author's strictures against the Government in the matter of unemployment. The Act of 1920 brought twelve million workers within the scope of compulsory unemployment insurance, which was a bold beginning, boldly made at a time when everyone knew a change for the worse was approaching. But for the miners' strike last year the increased benefits brought into force on March 3rd, 1921, might have been maintained. The conditions had since become more serious, so that he believed the Government would have to re-consider from its foundations, for the period of the present emergency, the conditions under which unemployment pay was granted. They would have to think not of the individual, but of the family or family group. Unemployment in normal times was a burden the State could bear, but when one had to deal with people who had been unemployed not for two and a half or five weeks, but for two and a half years, no normal method would meet the case. The burden was too great at the present time for the industries themselves to be asked to undertake it, although that might be the ideal method.

It was possible that, instead of a centralised bureaucracy at the Ministry of Labour, some attempt might be made on the lines of what had been done in regard to local educational authorities in the big towns. Local industrial authorities might be established on which the employers and trade unions might be represented, so that in every industrial area there would be a competent statutory body capable of dealing with all the problems that arose. In his opinion, the great problem before the country to-day was that of decentralisation, by which he did not mean sending officials from the bureaucracy

in London to the provinces, but cutting down the bureaucracy in London by passing on its functions to autonomous local bodies in the provinces. The policy of "give, give, give" and "take, take, take," meant that all the money of the country circulated through Parliament, through Westminster, which meant that much of it was wasted there and on the way up and back, maintaining hordes of bureaucrats. That money ought to be spent locally by local bodies, and, although that might mean a complete reform of our local government system, there was no reason why that should not be undertaken. The nation was, although tired, in a constructive mood, and was crying out for decentralisation, although nothing, so far, had been done. Autonomous local bodies with real powers and control of money were wanted; the Chancellor of the Exchequer and the Treasury should be steadily deprived of their money functions, and those vested in local bodies; otherwise the temptation to corruption in the central government and the evils which arose from ignorance and inefficiency would only grow.

MR. CECIL WALTON (of Messrs. Lever Bros) said he had travelled up that day from a little village in Cheshire called Port Sunlight. His firm had many battalions of people working for them there, while in their overseas plantations and concessions in various parts of the world they employed countless thousands. It was his duty—or, as he preferred to say, his pleasure—to control that great mass of labour, and he was therefore in constant touch with the grave problems which that involved, and in constant touch with the trade unions and all their activities. He had a very great respect for the trade unions.

In 1913, a man in Dresden said to him: "We Germans realise that you English people are complicated thinkers, and we are doing our level best to encourage you in complicated thinking." He treated it as a joke at the time, but it had been borne home to him recently that the remark was true; the English were a nation of complicated thinkers. There was very little clear thinking in connection with industry in this country at the present time. Taking the question of wages as an example, the country was threatened with a great industrial calamity by a suggestion that the wages of engineers should be reduced to a certain level. Without entering into the merits or demerits of that suggestion, he might say the suggested reduction in the wages of those skilled men, who had served long terms of apprenticeship, would place them on a level far below that occupied by the unskilled labourer to-day. Only that morning he had suggested at a Conference, a reduction in the wages of a large body of unskilled men—a reduction which would, however, leave them far above

the standard offered to the engineers—and was told that it was a wicked and pernicious suggestion. During the last few days one of the Wage Boards had ruled that the unskilled labourers attached to electricians on railways should receive 13/6 a day, and the linemen on the railways a minimum rate of £1 2s. 6d. It was the complicated system of thinking on such matters, and the anomalies it produced throughout the country, which were causing all the trouble at the present time. Wages and hours of labour had nothing to do with the question which was really tied up with production. During the war, this country multiplied its effort by something like fifteen times, but as soon as the war was over it reverted to pre-war practice in that respect. If the country would only double its productive effort now—which could easily be done—the question of wages and hours would not come into the picture at all. During the war a great army of unskilled men and women were taken into industry and trained, serving, as it were, an apprenticeship. By the time the war was over they were, if not fully skilled, at any rate semi-skilled, and they objected to being disbanded. As a result the unions were split into two camps—craft unionism and trade unionism. The great question to be decided at the present time was whether industries should be governed industrially or governed by the craft unions. To imagine that because trade unionism was at the present moment under a cloud, it would never come back in its strength was a great mistake; it would come back stronger than ever. The wise employer and the wise union would take advantage of the present period of comparative peace to put their houses in order, so that if all that was bad in craft unionism came back it would be found to be unnecessary. If the trade unions came back not as antagonists but as assets, there was nothing on earth that could stop them from coming into co-partnership in industry.

The question of measures for the prevention of unemployment was a great field which might, with advantage, be explored. Personally, he had given a great deal of consideration to that matter during the last twenty years. If the unions were to be asked to give up much for which they had—and rightly—fought, and allow full and unfettered production, they had a right to ask for something in exchange. The wise employer would say: "If you will give us this, we will guarantee you against unemployment." That could be done, in his view, quite easily. It could not be done out of profits, which were required for something else, but might be done in the following way. Suppose the output of a certain business was x , and the establishment charges were a certain figure. Those establishment charges would vary a little, but only a very little, with any increase of x . The increased effort which must reduce

those establishment charges would create a fund, part of which could be set aside as a guarantee against unemployment.

So far as his own firm was concerned, under the lead of his great chief—who, incidentally, he considered was the greatest industrial leader the world had ever seen—they were going to devote their time to caring for the human element in their industry in the same way in which they cared for the mechanical element. It was his duty to look after those people, and he found a very great joy in doing it. When one saw them all gathered together in a large hall, where one could talk to them not as official director of a company but as a man speaking to men, one felt that a great crowd like that was the most wonderful instrument in the world, and if one only played on it carefully one could extract the most wonderful music.

MR. R. McLAUGHLAN (London District Organiser, Electrical Trades' Union), thought superficial, rather than complicated, thinking was one of the difficulties with which this country was faced at the present time. That man's activities, whether political, religious, or judicial, are determined by the method whereby he obtains his livelihood is not yet generally recognized. The author suggested that the trade union movement should cut itself clear of any political party, but a concrete manifestation of the fact that political activity was a reflection of economic interest was provided by the representation of the Federation of British Industries in the House of Commons to-day. If it was logical and sound for one class to have that representation, it was equally so for the other class. The power of the trade unions to get to grips with the questions which faced them was impaired by the fact that their members had not had the facilities for education which were necessary to give them the power of analysing the problems with which they had to deal. Professor Huxley once said it was a crime to give a man a vote unless one gave him the power of understanding how to use it, and with that he agreed. It was illogical, however, to expect the employers to have any desire to place in the hands of the working classes a weapon which would enable them to emancipate themselves. The author referred to the "fanatics and scoundrels" who were responsible for such propositions as that put before the trade unions in the mines dispute. If, however, he took the trouble to analyse that proposition he would find that it was the result of outside conditions over which no one connected with it had any control. The Chairman, in dealing with the "Ca-canny" movement, and the resultant increase of price to the consumer, had not mentioned one factor which controlled prices, namely, cost of production. The real evil, in his view, arose from the fact that production was carried out socially, ownership being individual, from

which arose an antagonism, *i.e.*, "The Class Struggle." Under the present condition of society, there was no possibility of any mutual understanding between capital and labour. However much employers might desire to bring about this mutual understanding, they were face to face with an economic factor over which they had no control. Both labour and capital were part of a great system which controlled them rather than being controlled by them. That would continue to be the case until production for use was substituted for production for profit. When that came about there would be no need for trade unions or employers' associations.

MR. JOHN BAKER (Iron and Steel Trades' Confederation) complimented the author on his paper, which he thought was a valuable contribution to the subject with which it dealt. The author, however, knew him too well to expect him to agree with everything contained in the paper. He accepted the dictum that one had no right to meddle with a problem unless one tried to understand it. He believed the author had always accepted that principle, and it was unfair to suggest that "if he would take the trouble" to do something he would arrive at a different conclusion. It was not so much from complicated thinking or superficial thinking that the country was suffering, but from lack of thinking; people were not prepared to collect all the facts before arriving at a conclusion. The part played by the miners' strike in producing the present depression was exaggerated, and the fact that a similar state of affairs was prevalent in America, China, Australia—indeed, throughout the world—was overlooked. It had been stated that this country increased its productivity fifteen times during the war, but it must not be forgotten that, during that period of increased productivity, there was not a single moment when the workers did not have to fight to get an extra shilling added to their wages. Commissions of Enquiry, the members of which were presumably independent, had reported that it was the bread-and-butter question, the difficulty of existing on the wages paid, which produced the unrest then prevalent.

At a time like the present, when it was impossible to sell all that was produced, it was folly to ask the workers to produce more. In the trade to which he belonged, the relations between employers and men had been of a fairly friendly nature, and at one time they had discussed the possibility of making the trade responsible for its unemployed; but, before anything could be done, the slump came. At the time the matter was under consideration it was thought that 6d. a ton added to the price of steel would produce sufficient to permit of a reasonable allowance being given—not fifteen or twenty shillings—to all men unemployed; but, of course, that could not be done at the present time. Although, under present

conditions, the author's suggestion in that respect could not be put into effect, he regarded it as a valuable one. The employer who boasted that he was an employer should accept the responsibility of finding work for those who desired it, just as he expected a workman to do any work offered to him. The employer who asked a member of his staff to work over-time when an ex-member of his staff was unemployed should be ashamed of himself; the employer who claimed the right to manage his own works in his own way was claiming the right to control the lives of his workers, and such a claim was insupportable. The iron and steel industry should be run for the benefit of workers and employers alike. It was not to the advantage of the workers that the iron and steel masters should be ruined; the workers should take an interest in the management of the business, and try to extend it in all its ramifications. The workers must not have a policy which would ruin the works, and the masters must not pursue a policy which would ruin the men.

MR. J. J. HALL (Secretary, Silk Hatters' Trade Union) said that, besides being a worker—he had come from the bench that day—he was the Secretary of the oldest trade union in the world, a union whose charter went back to 1604 and which received Royal permission to associate in 1576. Trade unionism, therefore, was no new thing. History showed that trade unions should not rely on political effort alone: the greatest factor they could rely on was their own resources, financial and physical. If all the unions would work together, increase their subscriptions and place themselves on a reasonably sound financial basis, capitalists would be helpless. As soon as trade unions were made into political organisations corruption crept in. To substitute the State for private individuals as an employer would be a great mistake: it would destroy the initiative and individuality which had raised this country to the position it occupied to-day. During the war the State subsidised the workers at home at the expense of those who were fighting for their country abroad, and even had to bring workpeople over on holidays to France, to see the conditions which prevailed at the front, in order to get them to work. The employers themselves were largely responsible for the "Ca'-canny" policy the Chairman had mentioned. When machinery was first introduced, the employers found their men were making such good money on piece rates that they introduced the day rate. If the workman was playing "Ca' canny" it was the employer who taught him to do it.

MR. APPLETON, in reply, said he had been much interested in what the Chairman had said about decentralisation. He thought there was a good deal in it, but would like time to consider it. Mr. McLaughlan seemed to think

that the political activities of the Federation of British Industries disposed of the contention that it was a mistake for trade unionism to ally itself permanently with any one political party. That was not the case. The Federation was doing exactly what he would like the trade unions to do—using any party which happened to be in power and taking advantage of any circumstances which arose. The question of educational facilities was constantly being raised. In his opinion, there was no country in the world where the educational facilities were so good as in Great Britain: it was not lack of educational facilities but lack of educational inclinations which was the trouble at the present time. Personally, he was at school only on odd days and odd weeks prior to the coming into force of the Education Act. The educational facilities in those days were not very good, but he had taken advantage of them and would perhaps feel a little hurt if described as a wholly uneducated man. He was satisfied there was no justification for the whine about lack of educational facilities which was constantly being raised. He had served for nine years on an educational authority which literally went out into the highways and byways to get people to come in, but one could not keep them; although every inducement was offered they would not complete their courses. Some disappointment was felt on that account, and fear as to what would happen to a country where people refused to take advantage of the facilities offered. During the last twenty years he had not come across any hostility to education on the part of employers; they were much too astute to oppose the mental training of their workpeople; the man with a trained mind was a more valuable asset than the man with no mind at all or with an untrained mind. He opposed the general strike because a general strike involved all the people, and 95 per cent. of all the people were working people, who would be badly hit by such a strike, or even the threat of it. In 1919 the exchange with America had begun to go in favour of this country, when a sudden railway strike took place. That immediately arrested the change, and sent prices flying up again. One consequence of that was that Lancashire had to pay about two hundred millions a year more for her raw material than she would have done had the exchange been normal. The price of commodities was largely fixed by the buyer. The employer might try to get the highest possible profit and the workman the highest possible wages, but in a country such as this, where three parts of the people were dependent on overseas trade, prices were largely fixed by the overseas buyer. If our prices or quality were not satisfactory to him, or the goods could not be delivered when he wanted them, he would cease to buy, and unemployment resulted. He believed that the interests of employers and workpeople were, to a large extent, identical. While labour might be a commodity, it was also

capital, and, because it was capital, there was a certain affinity between it and its employers. He had no desire to see any class concentrate itself on purely class interests, because that meant the selfish subjugation of the other class, and, even if the other class was in a minority, that was unfair. It was all very well to say that it would be better to produce for use instead of for profit, but he could not understand why some of the mighty Empires of the past, some of those great brains to which we still paid homage, had not discovered the method of doing this a thousand years ago and put it into practice. In regard to unemployment, the fact was sometimes overlooked that in France there were less than 10,000 persons unemployed, and in Germany he thought, only about 36,000. When one remembered the size of the population of those two countries, it made one wonder what was wrong in our industrial arrangements. It was the country's business to find out what was wrong. He would like to remind his audience that a hundred years ago the House of Commons was discussing the question quite as intelligently as it was being discussed to-day. Incidentally, if the State became the employer there would be more need for trade unions than ever before. Unless the cause of our present troubles was ascertained and removed, we would go out of existence just as surely as did Greece and the other great Empires of the past.

THE CHAIRMAN, in proposing a very hearty vote of thanks to the author for his paper, said the method he had adopted in dealing with his subject should serve as a model to other investigators. No man in all England had a better knowledge of everything connected with the trade union world and the life and opinions of the wage-earners than the author, and to the study of those things he brought real thought and largeness of mind and patience. Unlike many who concerned themselves in economic and industrial questions, who seemed to have been born in the first year of the war, he had a wide knowledge of history, and had shown how to take a long and wide—and therefore a wise—view of the problems which confronted this country at the present time.

The vote of thanks was carried unanimously, and the meeting then terminated.

MR. E. C. DE SEGUNDO writes:—

Mr. Appleton well reminds us that "the right to discuss a subject involves the duty of trying to understand it." There are few matters upon which the average man is less well informed and less capable of forming a balanced judgment than upon the proper relations between "Capital" and "Labour." This is largely due to the fact that information upon the questions at issue is only obtainable by the

general public from *ex parte* statements on either side. Mr. Appleton's book, "What we want and where we are," constitutes a valuable contribution to the literature on the subject. Controversy between "Capital" and "Labour" will never convince the public of anything except of the existence, or rather the persistence, of antagonism between the two, and will assuredly not help to "encourage that mutual understanding between Capital and Labour, without which"—and here Mr. Appleton strikes the keynote of the whole matter—"neither can be even reasonably successful."

How is this mutual understanding to be brought about? Mr. Appleton answers this question in his book to which I have already referred. He says, "The treatment of unrest must be educative as well as palliative." Any system of education which sets the material above the moral is self-condemned." He criticises our present system of education—and I think justly—in the following words: "Unfortunately, the profoundly important work of training the young has been left too much in the hands of the bureaucrat and the professional. We have, in consequence, a people possessing a superficial smattering, but little love of knowledge for its own sake; a people who know little about themselves or about the facts which govern life."

The necessity for close and intelligent co-operation between Capital and Labour and the joint co-ordination of their respective resources has become very vital in view of the fact that only by the re-establishment of trade and industry, and particularly of our foreign trade, can we hope to persist as a nation.

In this connection, the problem of unemployment (of capital as well as labour) stands prominently in the foreground. All that Mr. Appleton says is very true. Unemployment of labour arises from a multitude of causes and can never be wholly eliminated under any conceivable form of social economy. But the present extent of such unemployment can certainly be mitigated, and to this end it would be well if trade unions would consider it one of their proper functions to act upon Mr. Appleton's advice and "tell the people the real truth about production and wages." This will, no doubt, involve some very distasteful lessons for workers, be they workers with their hands or with their heads. It will mean demonstrating, and acting upon (I don't know which will be the more difficult), the common-sense axiom which lies at the root of all sound economics, that *you cannot get a quart out of a pint pot*. Any section of the community which is in a position to render indispensable services can, by combination and organization, extort remuneration for service on a scale exceeding the economic limit for a time. In the long run, however, goods and services fetch what they are worth and no more. You can only *apparently* get a quart out of A's pint

pot by surreptitiously adding the contents of B's pint pot. The price of a commodity or the remuneration for service can only be kept above the economical level at somebody else's expense. As is evident enough to-day both in this country and in the United States, the continued raising of service-remuneration and lowering of service-value rendered, has brought in its train the Nemesis of inexorable economic fact—the unemployment of labour and of capital.

Both capital and labour overlook the truism that for every seller there must be a buyer. If buyers cannot themselves earn sufficient to pay the price for commodities determined by the rates of remuneration capital and labour fix for themselves, they go without, or reduce their purchases to a minimum, and it is obvious that both capital and labour sooner or later find themselves out of their jobs. The United States possesses about forty per cent. of all the gold in the world and immense credit; but she has some 5,000,000 unemployed. Great Britain has little gold but some £2,000,000,000 of credit entries in the books of the Joint Stock and other Banks. She has nearly 2,000,000 unemployed. In the meantime, would-be buyers the world over, are screaming for the products of capital and labour—at a price within their reach.

In a paper I read in this room in February, 1921, I pointed out that without the vitalizing element of directive ability, capital and labour are inert, though indispensable, factors in wealth-progress. Mr Appleton supports this view in his book. He says: "The enterprise of the thinker and fighter made possible the extraordinary increase in population (in England and Wales) which took place between 1801 and 1901." Lenin has at length admitted (*vide the Socialist Review* for January of this year) that his economic policy in Russia is a failure; that "the re-establishment of capitalism is radically bound up with our new economic policy" and that "the entire national economy must be based upon self-interest."

There is, however, one view-point which is often overlooked. The possessors of directive ability stand in a category by themselves. The exercise of ability is called into being solely by the stimulus of suitable inducement. Coercive measures operate only to dry up the well-springs of such inspiration. Now, I do not wish to be misunderstood in quoting Mr. Frederic Harrison who pointed out that "there is no case on record of a body of workmen creating a new market, or founding a new enterprise." This is no reflection upon the labourer, in the familiar sense of the term. It is not the job of the employed to undertake the speculative forms of activity and the risks inevitably involved in the establishment of new enterprises. But all ages, including our own, are full of instances of men in all ranks of life who have risen from humble beginnings to positions of power and

influence. Mr. J. H. Thomas is reported to have said in the House of Commons on February 24th last that "He believed no country was more democratic than our own, and that the Constitution that enabled him to leave the foot-plate and take his place in Parliament was one that gave democracy all that it required."

In a recent lecture I ventured to draw attention to the loose thinking which is responsible for much of the misapprehension and misconception lying at the root of the bitter feeling between "Capital" and "Labour." I suggested the following definitions:—"Capital properly denotes anything, or combination of things, non-material as well as material, capable of being turned to useful account in the attainment of a desired end by means of directed human activities, and labour properly includes all such directed human activities, mental as well as physical, as are involved in the attainment of such end."

I venture to think that these definitions are true and are calculated to dispel the widely prevalent and deeply rooted illusion that capital and labour subsist in water-tight compartments, so to speak, and that their interests are inherently antagonistic.

The ideals outlined in Mr. Appleton's paper and further elaborated in his book indicate that the most commendable motives underlie Trade Unionism, and Mr. Appleton, in common with many other leaders, deprecates the principle of attempting to solve economic problems by political action. We have seen, however, that the highest motives and the best intentions may be nullified where it is possible for extreme views to gain an ascendancy over mature judgment, and everyone would be glad to hear from Mr. Appleton that among the proper functions of the New Trade Unionism there will be included the form of education which he advocates so strongly, namely, the development in the members, and particularly the younger members, of that sturdy, healthy, moral sense which is the characteristic of the British Nation, coupled with the inculcation of a knowledge of *realities* as distinguished from academic theories; to the end that a recurrence of any concerted action so foreign to true Trade Union principles as that which caused incalculable loss and damage to trade and industry in the spring of last year, will become impossible.

I wish we had more Appletons in "Capital" as well as in "Labour." Those who know Mr. Appleton's work and his writings will agree with me that his attitude towards industrial questions is ever one of fearless and uncompromising honesty of purpose, and if the formulation of the proper functions of trade unions and the power to carry them into effect were vested in men like him the community would have no reason to fear the extension of the influence of Trade Unionism.

NOTES ON BOOKS.

THE PERIODS IN INTERIOR DECORATION. By Herbert Jeans. London: The Trade Papers Publishing Co., Ltd.

This handbook forms one of "The Decorator" series of Practical Books, which is edited by Mr. Arthur Seymour Jennings. The series has already established a reputation for itself as providing sound and well written text books for the various trades for which they are intended. Mr. Jeans's volume is designed for decorators, and gives a concise but adequate review of the principal styles of English decoration from Tudor times to the day of Morris. It is to be feared that the need for such a handbook is only too great. The average decorator has but the foggiest notion of "periods," nor does he seem to take any interest in the magnificent traditions of his callings. We should like to place Mr. Jeans's text book in the hands of every decorator, and when he has studied it, make him spend some weeks in the Victoria and Albert Museum, which, as Mr. Jeans's reminds us, has well been called the "Decorator's Paradise."

The book concludes with an interesting chapter on the progress of paperhangings in England, by Mr. Metford Warner.

DISTILLATION PRINCIPLES AND PROCESSES.

By Sidney Young; with the collaboration of Lieut.-Col. Briggs, T. H. Butler, Thos Durrans, the Hon. F. R. Henley, James Kewley, and Joseph Reilly. London: Macmillan and Co. 1922. 40s. net.

The special value of this important addition to chemical literature rests in the admirable interassociation of practice and theory, numerous distillation devices being figured and elucidated by the light of modern knowledge, while the kinetic principles which bear on the possibility of effecting fine separations by fractional distillation are well explained in words, in mathematical study, and also are embodied in tabular form for convenient use.

Chapter X is typical of that feature which we refer to above as "admirable interassociation." The chapter opens with a drawing and description of a fractionating still head figured by Ustadius in his *Liber de Secretis Naturæ*, printed in 1553; then follows a note on the inefficiency of the plain still-head, another on Brown's formula, and a longer study of the theoretically perfect still head—which, like Carnot's Heat Engine, cannot exist as a concrete embodiment. Dr. Young next touches on the characteristics of a good still head, the comparison of still heads, mixtures, influence of rate, use of pendulum to secure even rate of dropping, explanation of tables, influence of length and width, and observations on the many existing forms. References to sources, authorities and papers containing collateral or supplementary details are given in foot-notes or otherwise.

The above is typical of the whole range of over 500 pages with 210 illustrations; about half of the book, being devoted to the laboratory aspect, and half to special industrial applications.

THE OIL ENCYCLOPEDIA. By Marcel Mitzakis. London. Chapman and Hall, Ltd 1922. 21s. net.

This is a practically useful reference book for those having to do with mineral oils or the like; and as it is in the dictionary form, with such cross references as are necessary, no formal index is required. The pages (large octavo), are a little over five hundred, and as an average we take it there are five or six articles to a page, but important subjects have adequate space, oil engines being treated of in four pages, and oil fuel in a trifle over four. A concise and lucid style, together with the fact that many references are given to the larger text books or specialised treatises, makes the work before us a convenient desk companion for the busy man.

It is, in short, a ready reference volume, without undue technicalities which should be at hand in every business establishment connected with the petroleum industry.

RESEARCH IN INDUSTRY: THE BASIS OF ECONOMIC PROGRESS. By A. P. M. Fleming and J. G. Pearce. London. Sir Isaac Pitman & Sons, Ltd 1922. 10s. net.

There is a tendency, in the book before us, to make confident assertion in highly controversial matters. Thus (p. 1), we find a statement "Sociologists are agreed that . . .," the issue being our author's contention that ethical or moral progress is sequent to and consequent upon, material progress (pp. 1 and 2). These issues, and the question as to the moralising or demoralising influence of science (the habit of knowing) and of art (the habit of making) have, as far as we read history, been the most discussed of all the fundamentals of economics, and the issue on which there has been the most even division of opinion. The difficulties of associating that first element of morality, unsoiled verity, with certain details incidental to manufacturing and salesmanship, are obvious; putting aside ancient studies and the confident view of Ovid when referring to the golden age and his modified view with respect to liberal art (poesis, or the habit of making, in the higher sense, i.e., without constructive material, and, broadly, including literary invention, verification, music and design). This is considered by Bacon (p. 66 of Bohn's English Version of Bacon's Chief Works); but turning wholly on the word "*fideliter*," the conclusion being otherwise reversed. Herbert Spencer was, perhaps, the first to apply quantitative analysis to data bearing on this matter (see his study of Sociology, eighteenth edition, London, 1879, pp. 439-440). From the general standpoint reference may be

made to Lecky's History of Morals, especially Vol. II., Chap. V.; also to the Encyclopedia of Social Reform by Bliss, New York and London, 1897, pp 895 and 896; The British Supplement to Bliss (1908), containing notable articles, especially under the headings Adulteration and Illicit Commissions.

That the spontaneous research work of the zealot who publishes unreservedly, has acted favourably on industry as a whole, appears to be beyond question; but such associated research as that which appears to have been carried out at the expense of the affiliated aniline-colour firms in Germany, seems to have had sinister results which the world is now experiencing—despite large pre-war profits to the interested firms.

Whether difficulties can be overcome by any such highly complex ordering of matters as that suggested in the book before us, appears to be problematical, as, apart from all questions of honest aims in the specialised research or uncandid items in publication, the incidence of the laws of increasing or diminishing returns (changes of ratio between effort and result), cannot easily be predicted. (See Walker's "First Lessons in Political Economy," Macmillan, 1890, pp. 25-33.)

The work before us may be studied with advantage by matured students of economics, who, it may be assumed, have taken to heart Bacon's cautions as to hesitancy in accepting the first offer of things.

THE COTTON TRADE AND INDIA.

The following views on the future of the Lancashire Cotton Trade by SIR CHARLES MACARA appeared in a recent issue of the *Manchester Guardian*:-

"I am sorry to see some of the operatives taking so gloomy a view because it seems to be based on a misconception of facts. Take the present position of the Indian cotton spinner and manufacturer. In India there are now about 7,000,000 spindles to meet the requirements of a population of more than 300 millions. It takes about 12 millions of our 60 million spindles to meet the needs of our people at home. And it has taken India well on towards a century to get its 7,000,000 spindles. We have to remember also that the Indian spinner is greatly handicapped in his initial outlay. Where before the war it cost us at the rate of two guineas a spindle to put up our mills, it cost the millowner of Bombay four guineas, and the proportion is about the same to-day.* No doubt a great deal of the machinery now going out to India from this country was ordered before the war, but it will have to be paid for at the enhanced prices.

* The cost of erecting a Ring Spindle Mill in England to-day is about £7 per spindle. In India the cost would be nearer £14 per spindle.

"It has been complained that Lancashire spinners and manufacturers have to contend also against longer hours and lower wages in the Indian mills. That is true, but things are not as bad as they appear. England has led the world in reducing hours of labour. Here and in America hours in the cotton industry have been reduced from 55½ to 48 a week, but the Continent is following the example; India has just reduced its hours from 72 to 60, and night-work is to be abolished in Japan. And the process will continue until there will be uniform hours of work throughout the world. The reduction of 12 hours in the Indian mills will go a long way towards counterbalancing the difference between the import and Excise duties. Then, although the individual worker in Indian mills gets much less than the Lancashire worker, he is nothing like as efficient. One Lancashire operative is probably equal to three Indian, so that really the wages bill is not so small in comparison as many people imagine. A prominent Japanese told me that in his country they have to provide houses, music-halls, and theatres and do a variety of other things in order to attract people into the mills. Another item which is by no means negligible in the running of cotton mills in the east is the damage done to machinery by shocks of earthquake.

"Altogether then, prospects for the Lancashire cotton industry are not as bad as some people would have us believe. It will be a very long time before India will be able to do without English cotton goods. There are many millions of people there who have used very little clothing at all as yet. And look at the possibilities in China, with its population of 500 millions and only about 2 millions of spindles."

GENERAL NOTES.

PURCHASING POWER OF THE NATIVE POPULATION OF INDIA—The United States Trade Commissioner in India reports that, as a result of an investigation made by the director of agriculture in Gujerat, a region in the Bombay Presidency supporting a population of 9,000,000, the native family of three adults and two children of the class owning small holdings of land spends annually 228 rupees. The expenditure of the field labourer is, of course, less. An investigation in the region of the Deccan revealed that only 35 per cent of the families were entirely self-supporting. The chief demand for imported goods, except for cotton clothing, comes from landed proprietors, money lenders, merchants, and city dwellers, though the purchasing power of this class has not been estimated. The growing industrialization of India will, however, undoubtedly eventually effect changes in the economic condition of the native population.

BRAZILIAN CENTENARY EXHIBITION—An excellent opportunity for British manufacturers and merchants to extend and open up new business in South America is offered by the Brazilian Centenary Exhibition to be held at Rio de Janeiro from September 7th to December 31st next, in celebration of the centenary of Brazilian independence. The British section is being organised by the Department of Overseas Trade. Brazil, in common with the other states of South America, all of which will have buyers at the exhibition, possesses immense possibilities for the future, little as yet having been done to develop its enormous resources. Britain's chief competitors there are the United States of America, who have voted one million dollars for official participation, and France and Belgium who have also voted large sums for the same purpose. Practically every country in the world will be represented. British firms will therefore do well to avail themselves of the facilities created by the Government's acceptance and vote of money for participation in response to the invitation of the Brazilian Government. Full particulars can be obtained on application to the Department of Overseas Trade at 35, Old Queen Street, Westminster, S.W.1

JAPANESE PRODUCTION OF CULTURE PEARLS—According to a report by the United States Acting Commercial Attaché at Tokio, culture pearls are now being produced in Japan on a small scale by several companies, while one company is producing a variety which is very similar to the natural article. Some of these culture pearls are round and entirely coated, though most of them are flat on the back, where they are attached to the mother-of-pearl shell. It is stated that pearls are secured from about 80 per cent. of the oysters treated, and that they sell for approximately 30 per cent. less than the natural variety. While the production of culture pearls in Japan is evidently on a successful commercial basis, it is not probable, adds the Attaché, that this production, which involves a slow and costly process, will be large enough to affect the price of the natural product.

QUININE CULTIVATION IN THE PHILIPPINE ISLANDS.—According to the Director of the Philippine Bureau of Science, large available areas in Luzon and Mindanao Islands are highly adapted for quinine cultivation. At present there is one small quinine plantation in Baguio, which is under the supervision of the Bureau of Forestry, and the results obtained from its operation indicate the success of the industry. Climatic and general conditions in the Philippines are very similar to those of India, where there are quinine plantations contributing about 10 per cent. of the world's output, and to those of Java, which supplies about 90 per cent. of the world's output.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 p.m. (unless otherwise announced):—

APRIL 26.—**JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E.,** "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry." **SIR JOHN F. C. SNELL,** Chairman of the Electricity Commissioners, in the chair.

MAY 10.—**MAJOR PERCY A. MACMAHON, R.A., LL.D., ScD., F.R.S.,** "The Design of Repeating Patterns for Decorative Work." **SIR CHARLES CARRICK ALLOM** in the chair.

MAY 17.—**OSWALD M. SHEPARD,** "Recent Developments in Rubber Manufacture, with special reference to Rubber Machinery and the Manufacture of Tyres."

MAY 24.—(**GEORGE FLETCHER,** Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland.")

MAY 31 (at 4.30 p.m.)—**LAWRENCE HAWARD, M.A.,** Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock:

APRIL 28. **F. G. ROYAL-DAWSON, M.Inst.C.E.,** "The Need for an All-India Gauge Policy." **SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B.,** in the chair.

MAY 26. **SIR THOMAS W. ARNOLD, C.I.E., D.Litt., M.A.,** Professor of Arabic, School of Oriental Studies. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced:

J. T. MARTEN, L.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION

FRIDAY, JUNE 9, at 4.30 p.m.—**MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E.,** "Tanganyika Territory (formerly German East Africa)."

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

JOINT MEETING.)

Friday afternoon, at 4.30 o'clock:—

MAY 5—**PROFESSOR WILLIAM HENRY ECCLES, D.Sc. (London), F.R.S.,** Vice-Chairman of the Wireless Telegraphy Commission, "Imperial Wireless Communication."

Journal of the Royal Society of Arts.

No. 3622

VOL. LXX

FRIDAY, APRIL 27, 1922. 18 MAY 1922

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, APRIL 26th, at 8 p.m. (Ordinary Meeting). JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry." SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the Chair.

FRIDAY, APRIL 28th, at 4.30 p.m. (Indian Section). F. G. ROYAL-DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the Chair.

Further particulars of the Society's Meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

SIXTEENTH ORDINARY MEETING

WEDNESDAY, MARCH 15TH, 1922.

SIR ROBERT MOLESWORTH KINDERSLEY, G.B.E., in the chair.

The paper read was:—

CERTAIN ASPECTS OF THE PROBLEM OF EXCHANGE STABILIZATION.

By OSWALD T. FALK, C.B.E.

I shall discuss in this paper the problem of the stabilization of the gold or dollar value of sterling. If this subject is narrower than the title of the paper suggests, I must plead forgiveness on the ground that I had to choose the title before the paper was written.

In January, 1918, the Cunliffe Committee was appointed to "consider the various problems which will arise in connection with currency and the foreign exchanges during the period of reconstruction and report upon the steps required to bring about the restoration of normal conditions in due course." The two reports of the Committee were published in the autumn of 1918 and at the end of 1919. Very little thought was given to the difficulties of the reconstruction period; it was assumed that the pre-war financial system was the goal to be aimed at, and attention was directed almost exclusively to a rather doctrinaire and rigid scheme for the attainment of this goal. Worst of all, the Committee made the mistake of discussing the problem from the point of view of finance rather than from the much more important point of view of industry, trade and the general welfare of the community. Our financial policy since the Armistice has not been a success, and for its failures the Cunliffe Committee are partly responsible.

But the sins of the Committee were mainly sins of omission, and it has not been any real or assumed obligation to obey the precepts of the reports which has caused the Treasury and the Bank of England to make their chief mistake of the last three years. During this period we have suffered from a wild boom, a disastrous slump and prolonged depression. A boom, a slump and depression we should have suffered in any case, but all three might have been less acute if those in control of financial policy had used the discount rate wisely. Bank rate was raised much too slowly during the boom, and lowered too late and too slowly during the slump. The rate ought to have been at its present level months ago, and to-day there is as much justification for a 2 per cent. rate as there was in the years following the Baring crisis. In times such

as these, when our currency is inconvertible, and exchange far away from the level regarded as the ultimate goal, the discount policy of the Bank of England cannot be operated satisfactorily if those in control fix their attention primarily upon the volume of currency and bank deposits, the reserve, and the premium on dollars. They must remember that it is their duty to endeavour to prevent booms and slumps, and to keep the standard of value as stable as possible. Since the Armistice, with this object in view, they should have regulated the discount rate in accordance with the direction and rate of change of the internal commodity price level.

The Federal Reserve Board of the United States has made the same mistake, though for rather different reasons. The policy of the Board has been very ably criticised by Mr. Hawtrey in a paper read to the Royal Statistical Society last month. "The whole world," says Mr. Hawtrey, "has been plunged into the most appalling distress for nearly two years by the strain of raising the commodity value of the dollar 80 per cent." I agree with him that this was unnecessary, and that it was due to a failure on the part of the responsible authorities to understand what he calls the vicious circle of deflation. If he were not an Assistant Secretary of our Treasury, Mr. Hawtrey might have extended his criticism to the policy of those in control in this country, for we need not be dragged at the heels of American error.

This past history is important, because it throws some light upon the mentality of those responsible for dealing with the present and future problems which are the main concern of this paper.

Bank rate in London is now (27th February) $4\frac{1}{2}$ per cent., the rediscount rate of the Federal Reserve Bank of New York also $4\frac{1}{2}$ per cent., and the New York-London exchange 4.42. I have said that in my view Bank rate ought to be 2 per cent., and that London need not wait for American reductions. On the contrary, the rapidity of the recent rise in sterling is a very strong reason for putting London rates below New York rates. The rise is harmful to our trade, and we ought to check it, not stimulate it. If we are to aim at restoring the pre-war parity with the dollar, let us stimulate the rise in sterling when trade is booming, not when it is in the depths of depression. We can more easily afford to check a boom

than to knock trade on the head when it is trying to get on its feet again.

I do not propose to discuss the question of devaluation. At present the discount on sterling is being so rapidly reduced that the restoration of the old parity appears within easy reach, but in a few months' time the rate may fall away again, and devaluation may in the end become desirable, if not inevitable. If we were to attempt to stabilise sterling immediately we should have to devalue, but, an immediate choice being unnecessary, all we need do is to make up our minds not to damage our trade by a financial policy designed to restore the old parity at an early date.

The problem of maintaining exchange stability is quite different from the problem of fixing and attaining the level at which stabilization is to be attempted.

There are, in my opinion, three important preliminary conditions of an attempt at stabilization :—

- (1) A practicable settlement of the Reparation and Inter-Allied Debt problems.
- (2) A reduction in the size of the favourable trade balance of the United States, and the maintenance of this reduction for a considerable period.
- (3) A restoration of complete confidence in the ability and determination of our Government to balance the budget.

With these fundamental political and economic obstacles out of the way, we could turn our attention to the technical aspects of a difficult, though not impossible, problem.

The technical difficulties will probably prove greater than is generally expected, and it is essential that they should receive careful consideration before we take the plunge.

The account of this country with the rest of the world, is balanced to a half-penny every day. If there is anything owing either way after the payment of all debts arising out of sales of goods, services, gold, currency notes, and securities, the difference is settled by an international credit in the books of bankers. It is true that the attempts of debtors to settle the difference, or, in other words, to secure exchange which does not exist, cause exchange rates to move, and this movement not only alters the money figure of the old debts which are being settled, but also causes an offset by way of new sales of goods, services,

gold, notes, and securities within the day. Thus, in two ways a shift in exchange rates reduces the difference which is left over for settlement by bankers, but, in spite of this reduction, the final amount is at times a large one.

Before the War, seasonal and other temporary fluctuations in exchange were confined within the gold points, and the fact that they were so confined, though due primarily to the guarantees of the gold standard, was due, secondarily, to the willingness and ability of international bankers to settle the difference referred to above. But it must be remembered that any grant of international credit involves the creation of an open exchange position, and that bankers, as a rule, are unwilling to run the risks of heavy losses in exchange. Before the War, bankers settled the final difference, because they considered their risk of loss to be confined within the limits of the gold points. If we restore the gold standard, they will not shift balances for small exchange and interest rate profits, unless they have complete confidence that the attempt to maintain exchange within the gold points will succeed. Since the Armistice the banks have been able to settle the final differences in spite of fluctuating exchanges, because the necessary speculations in exchange have been made by other people. In fact, under present conditions, the initiative in settling the difference and checking an exchange collapse is taken by exchange speculators, the banks being now mere agents in the matter. If there were no people willing to speculate in exchange, the required credits would not be granted, and the exchanges would collapse. When we restore the gold standard exchange speculators will go out of business, and the burden of taking the initiative and acting as principals, will once more fall mainly upon the banks.

It is further to be noted that the final difference must not be too great for the credit granting capacity of the bankers, and we cannot assume that the daily adjustments required will now be as small as they were before the War. For both political and economic reasons, the trade disturbances are likely to be greater, and the assistance given by the movement of securities is certain to be less, partly because the credit of many borrowers is impaired, and partly because, with taxation at its present level, double taxation is a very

serious barrier to the transfer of securities from one market to another.

I, therefore, conclude that it will be very dangerous to attempt stabilization until we have assured ourselves both that the task of adjusting the daily balance is not beyond the capacity of bankers, and that the prospects of success are so obviously good that the whole banking world will feel confident about the result.

Another difficulty is caused by the large volume of Treasury Bills outstanding in this country. The machinery by which the Bank of England controlled the exchanges before the War would now be much less effective, because holders of Treasury Bills can force the British Government instead of foreigners to make good the deficiency in the reserves of our Money Market. The difficulty cannot be overcome quickly by funding Treasury Bills, because Treasury Bills are now an essential element in our internal currency and banking system, and their elimination can only be effected at the cost of heavy and harmful deflation. So long as there are Treasury Bills in the hands of the public and the Joint Stock Banks, the Bank of England will have to make very rapid and drastic changes of the rate of discount in order to produce any effect upon the foreign exchange position, and even so I very much doubt whether the discount rate will prove adequate. Some new device may have to be summoned to our aid.

A third difficulty may arise if the debts owing to our Money Market by foreigners are different in size or type from what they were before the War. Under pre-war conditions the rapid protection which we sometimes required for our gold reserves was supplied mainly by calling these foreign loans. If such loans are now smaller in volume as compared with our normal daily foreign account, or, though as large in volume, of longer average maturity, it is obvious that they will be a less effective instrument than they were for protecting our gold and correcting the exchanges. I am not able to express any decided opinion upon our present position in this respect, but I think there are good reasons for suspecting that the strength of our foreign claims portfolio has decreased. It is, in any event, a question which requires very careful consideration.

We must also remember that foreign claims upon us are more important than they were before the War. In 1914 prac-

tically the whole world with the exception of France owed us money on balance on short loan contracts, and the United States were at our mercy when we called our loans at the outbreak of war. To-day the United States are in a very different position, and the task of protecting our gold would be extremely difficult if they were to call the loans which they have made to other countries.

A fourth difficulty is provided by the uncertainty as to the sufficiency of the world's gold stock for the support of the present volume of currency and credit measured in terms of gold. The world's stock will certainly not suffice unless all countries use gold very economically. It is, therefore, very unwise to suggest, as the Chancellor of the Exchequer has done, the possibility of a resumption of the use of a gold currency in circulation in this country. If we want to have a free market for gold, we must devise some plan for establishing such a market without allowing gold coin to return to the pockets of the people. The alternative to economy in the use of gold is a further severe fall in commodity prices, a disastrous solution which should be avoided at almost any cost.

We have discovered during the last few years that the welfare of the whole community depends very largely upon monetary policy, but, in spite of this, it is hardly an exaggeration to say that we now have no policy at all. The pre-war policy will not work under post-war conditions, the Cunliffe Committee Reports provide little guidance in our present troubles, and we are, therefore, leaving everything to the Treasury and Bank of England, who are better fitted for the work of operating an old policy than for the very different task of devising a new one. We are sailing uncharted seas, and at each stage of our progress we need the guidance of men whose ideas about money extend beyond the narrow limits of pre-war inductions. It is above all things essential that our problems should be submitted to a fresh committee on currency before we attempt a return to the gold standard. If this is not to be, then may Heaven deliver us from the Norman Conquest of 4.86½.

DISCUSSION.

THE CHAIRMAN (Sir Robert Molesworth Kindersley, G.B.E.) said that when he was asked to take the chair the subject given to him was "Certain Aspects of the Problem of Exchange

Stabilisation." That was a very wide problem indeed and might embrace other problems of exchange which would be just as difficult as the question of sterling dollar exchange only. Perhaps the author might have thought he would be able to draw him to do battle on the occasion on behalf of the Bank of England, but if by any possible chance that was the author's idea, he was afraid he would be disappointed, because as the paper had taken rather a personal turn in regard to the Bank it was not possible for him, as a director of the Bank of England, really to enter the lists in a serious way. He did not intend to do so because, if he did, he might be considered to be interpreting the views of his confrères in the Bank and he did not wish to be considered in that light. He was like the gentleman who, when threatened by the Black-hand gang in New York, that if they did not receive 20,000 dollars they would murder his wife, wrote back and said he could not possibly give them 20,000 dollars because he had not got them, but their proposition interested him! He thought that was really as far as he could go: the proposition interested him. He did not agree with the author in his statement that the American situation could be entirely disregarded by this country; nobody who was in a responsible position could adopt such an attitude. On the other hand, the author had stated that the Bank rate might just as well be 2 per cent. as 4½ per cent. To such lengths he did not go, but he would like to state what he had felt for a very long time that probably one of the most important consequences of the war was the extraordinary loss of the sense of proportion in every walk of life. In considering what was dear money and cheap money the world had really lost its sense of proportion. People were inclined to think money was cheap when they talked of 4½ per cent., and so it was but only by comparison with the previous high rates, but the sense of proportion in regard to that particular matter had suffered in the same way as with regard to other things. He disagreed with Mr. Falk with regard to the American situation, feeling that the American rates must to a large extent govern the London rate. It was necessary not only for this country to get back a sense of proportion in regard to what was cheap money and what was dear but also for America to do the same. It was necessary for both nations to march along the same road. The paper had taken a somewhat personal turn so far as the Bank was concerned, and as a Director of the Bank he preferred not to deal with the subject in detail.

MR. F. E. STEELE said the Chairman had taken the line of the Scotch Minister who when faced with a theological difficulty said "We will look this difficulty boldly in the face, and pass on." He did not see how the Chairman, having regard to the position he occupied, could take any other line than that he had taken, however.

The fact remained, though, that before the bank rate was raised to 7 per cent. prices were rising rapidly in every direction and there was a regular orgy of speculation. Thursday after Thursday went by without the Directors of the Bank of England taking a step which would have checked some of that speculation and the undue rise in the price of commodities and so saved some of the misery which had since occurred through things collapsing. The Bank of England had in its hands a machine devised to check such evils, and that machine should have been used earlier. The raising of the Bank of England rate was like the red light which showed danger and the moral effect of raising the rate was important. Then, too, the high rate was kept on too long, being retained when prices fell. When the bank rate was maintained at a high level for an unduly long period it constituted a handicap on industry which was unnecessary and indefensible and on those points he very cordially concurred with the line that Mr. Falk had taken. There were three conditions of stabilisation given in the paper, one being that the reparation problem must first be got out of the way. What had to be settled was the amount to be paid, the method of payment and the division of the money among the various claimants. The last point had been emphasised during the last few days by the American claim. In all discussions about currency there was talk about the desirability of balancing Budgets, a very necessary thing, and about stopping the printing press, an equally desirable thing; he was absolutely convinced that until the question of reparation was settled on the lines indicated there would be never any stabilisation of exchanges. It was a point to which the earliest attention of the Government and of financial authorities should be directed.

SIR LANCELOT HARE, K.C.S.I., (L.E.), felt that not sufficient attention was given to the fact that as prices rose purchasers found their incomes insufficient to purchase and were bound to hold off buying and consequently traders and manufacturers had to consider whether they should hold on and compel people to have things at a high price or face a loss and continue to pay interest to their bankers or have their loans called in. Therefore, when people spoke of the bank rate causing deflation they were sometimes rather in the position of the fly on the wheel. The banker might think that by increasing the rate he was causing—and in a measure he was—prices to fall, but the main thing was that if the quantity of money was constantly being increased, prices were forced up without increasing the incomes of all the people. He had written a little book on the study of exchange [*‘A Study of Exchange,’* P. S. King & Co., Orchard Cross, 2s. 6d.], which he believed contained a true theory of currency. The old economists had always argued from

experience, and had said that currency was a medium of exchange and standard of value, but taking it synthetically it was quite easy to see that the currency could be enormously increased without increasing permanent incomes. A man promised £1,000 a year 20 or 30 years ago was now only getting the equivalent of £200 or £300, and sufficient attention was not paid to that part of the case. He thought the true solution was to be found in a proper system in which gold would be the coin but not at its full value, that the gold in the coin should be always less than the value of the coin for purchasing. Eventually it would be possible to work up to a system which was the aim of the old economists, that the value of currency should be fixed on the average of a great number of commodities, and not only upon gold. It was essential to get back to gold in currency and values must be at such a standard that the great mass of people whose incomes had not been raised should be able to purchase as they did before the war.

MR. CHARLES SELIGMAN said Mr. Falk had stated that Treasury Bills were to-day a necessary part of the banking outfit and that therefore he did not like to view the possibility of a repeated reduction of those Treasury Bills by too quick deflation. Would not that be entirely met if, on the revival of trade, Treasury Bills were replaced by the genuine trade bill, which was what the bankers wanted? Automatically the Treasury Bill would disappear as the trade bill took its place. With regard to the question of gold, the author had stated that it was a question in his mind as to whether there was sufficient gold in the world for the requirements of the world under the new conditions. Was it possible that something other than gold could have the functions of gold? During the process of reconstruction would not approved bills or approved securities deposited with the bankers do the work of gold until such time as the gold of the world had been redistributed amongst the countries in proportions necessary for those countries' work?

MR. ALFRED RORKE asked whether it was necessary or possible to re-introduce gold currency. Was not the main cause of the difficulties in exchange the fact that artificial wealth had been created by the banks of Europe and that all the difficulty was caused in the endeavour to justify that artificial wealth?

MR. CHARLES GANE asked the author if he could explain precisely what was meant by devaluation.

MR. FREDERICK WIGGLESWORTH said there was great necessity for a low bank rate for the export trade. Money was borrowed in this country by our foreign and colonial friends, and remitted in the form of goods, and thereby

trade was stimulated: and from that point of view it would be a great advantage to the country to have a rate lower than that of New York. America had all the resources to supply her own people with everything they required and was practically independent of export trade, but England could not live without export and if she modelled her monetary policy on that of New York she was almost bound to suffer in the competition. He ventured to suggest that it was possible to maintain stability of values, at least temporarily, without reference to gold, by maintaining internal values in this country as constant as possible and regulating the movement of the rates for money accordingly. The effect of the bank rate was much more to contract the velocity of circulation than actually to deflate. As a matter of fact the bank deposits were practically as large as they were when the bank rate was put up to 7 per cent., but what happened was that the whole position became solidified, and it was not until the rate was lowered to $4\frac{1}{2}$ per cent. that the position began to liquify, causing money to flow into the Stock Exchange. Gradually that money would find its way into the trade of the country, and thus restore industry.

SIR HENRY STRAKOSCH thought the importance of the bank rate policy of the Bank of England and the Federal Reserve system could be exaggerated, especially during the period which followed immediately the Armistice. The whole system of production, distribution and consumption suddenly changed from one of war to peace. There were huge stocks of certain commodities accumulated while other commodities were scarce, and there was a difficulty of intercommunication with the various countries so that merchants could not gauge the situation as in normal times. Then came the phenomenon which followed all wars—huge stocks of commodities held up by Governments, merchants and speculators, assisted no doubt by bank credits. The rise in prices which took place after the Armistice was almost inevitable and the slump which followed was equally inevitable. Forced sales had to take place. Whatever the bank rate had been in those days there would have been a glut of certain goods and a very severe slump. Then there was the complete loss of equilibrium in prices and wages. The wage level was far too high at that time to be able to replace what was consumed. Hence too curtailed production in many industries! Wages had to adjust themselves to the new price level before the wheel could start to turn round. That was a phenomenon witnessed from early in 1919 until the middle of last year. He very much doubted whether the money policy of the Bank of England or the Federal Reserve system could have changed very materially what had taken place.

MR. CECIL BROWN asked whether Mr. Falk did not think that the collection of gold in America was not, to a certain extent, affecting the stabilisation of exchanges. Was there any prospect, by trade or otherwise, of the enormous collection of gold, about two-thirds of the gold of the world, being distributed so as to stabilise exchanges? A short time ago when he was in America the industrial population hated the very sight of the gold that was stored up; it was doing nothing to earn money. Could not the nations who had paper currency have a certain amount of gold reserve against that paper currency?

MR. GEOFFREY MARKS said the suggestion made in the paper that a fresh Currency Committee should be appointed to consider the problems which came before the Cunliffe Committee in the light of existing conditions was one of the most important that could be possibly put before the Government, and he did not understand why the Government had turned down the suggestion. He thought it was perhaps the most important method that could be devised of discovering the necessary solution.

MR. M. KIPP drew attention to the very great improvement in the question of exchange since the Armistice. The eastern exchanges and the exchanges with the Colonies were beginning to function more normally and between the limits which existed before the war. The great fluctuations nowadays were in the American dollar exchange which reacted on the Continental exchanges and no stabilisation of the one was possible without the stabilisation of the other. A condition precedent to the return of the gold standard and the free exchange of gold was some arrangement with America for the funding of the present debt; otherwise America would be able to call in the whole of the gold as we accumulated it. He did not think the proposal to have a new Committee on Currency was a good one. The Committee on the Indian Exchange, he believed, was totally wrong in its findings. The question of currency was best left to find its own level guided by the rate which the Bank of England stated. If the Bank of England moved with prudence it was very much better than moving with too much haste.

MR. F. H. H. SIMPSON said one of the great difficulties in approaching the question of stabilisation was that it was necessary to stabilise the whole of Europe and America and not Great Britain only. During the war this country was paying a great price in order that Europe might obtain its dollars cheaply; Europe had to pay a greater price for what she required from America. The most extraordinary thing was that the play of financial affairs had brought the return of the dollar nearer to the value of sterling. The more one thought of the question the more one was forced to come to the con-

clusion that it was only by natural forces and not by anything artificial that we could get back to the stabilisation within the old original limits.

MR. A. F. E. FOUCAR considered that the main cause of the present troubles was lack of production. The law of supply and demand could not be violated. The buying power of a large proportion of the world had been enormously cut down, if not in many cases entirely eliminated, and that meant that the whole basis of international commerce, the exchange of one commodity against another or against services rendered, was nullified, and until the whole world settled down to work it was not possible to expect any real improvement in exchanges. The present state of the exchanges was merely a symptom of the disease from which the whole world was suffering. The eight hours day was an important factor in curtailing production on the one hand and the power of absorption on the other. Until people had realised that we had mortgaged the future by enormous issues of paper and that it was only by hard work we could get right, no real improvement could be anticipated. With regard to the bank rate, he thought people were a little apt to overlook the fact that the raising of the bank rate did not have the effect that it had in pre-war days when there was a free market for gold. Money was thereby attracted to this country and the exchange consequently moved in our favour.

MR. FALK, in reply, said it was very difficult to say anything about the Chairman's remarks. The one criticism he had made was that he did not think the suggestion that the United States could be disregarded was a sound one. At present America had tremendous reserves of gold and was unwilling to use them and she had pursued during recent months a policy of deflation which had been extremely harmful to the world. If we attached more importance to £.86½ than to the condition of our trade we should follow in America's footsteps. If on the other hand we thought more about our trade than about reaching the old parity he believed we should disregard what America did, and having our eyes mainly on our own prices we could well afford to bring our money rates below those of America. He was not sure it would have such a harmful effect on the exchanges as some people supposed. The Chairman apparently thought that money in the United States might be cheapened, and therefore agreed with the criticism in the paper, in so far as it was a criticism of the use of the discount rate in the two countries. He quite agreed with Mr. Steele that the reparation question and the inter-allied debt question were of first rate importance. He did not quite follow the whole of Sir Lancelot Hare's argument but understood one of his points was

that the paper did not deal with the fundamental question of the economic or social advantages of rising, falling or steady prices. He had more or less assumed as a major premise in the paper that steady prices were better than fluctuating prices. He agreed that in theory, use might be made of index numbers for the purpose of the standard of value, but it seemed to him an Utopian suggestion which could not be put into operation at present. With regard to Mr. Seligman's point about Treasury Bills, he certainly hoped that in the course of time Treasury Bills would be replaced by Trade Bills. His point in the paper was not so much that Treasury Bills could never be eliminated but that to do it quickly was an impossibility. It was impossible suddenly to create a mass of Trade Bills to replace Treasury Bills, and therefore, Treasury Bills could not be abolished by funding because what was put in the place of the Treasury Bills would not be a satisfactory substitute from the point of view of the banking system. With regard to the question of gold sufficiency raised by Mr. Seligman, he agreed that the difficulty might be overcome by replacing gold in part by bills. In fact one of the main points in the paper was that if we were to return to the gold standard we must economise in the use of gold. There were difficulties in devising new financial machinery for economising, and it was very undesirable to contemplate a return to pre-war practice in the matter of gold currency, which was the very reverse of the economy of gold. With regard to the question asked by Mr. Gane as to what was meant by devaluation, he meant by that giving a new and lower legal gold value to paper currency. A very important point was raised by Mr. Wigglesworth which went to the root of the discount rate policy, when he said he thought the main feature of the recent slump on the money side was a decrease in the velocity of circulation. That was absolutely true and most writers on money had not hitherto dealt satisfactorily with that point. They had allowed for the velocity of circulation in the quantity theory equation, but had not pointed out exactly what happened in a slump to the bank deposits. The deposits in this country had remained more or less constant for some time, but the advances had declined—in other words the inactive deposits were growing.

It was curious that people who defended the maintenance of high rates for money pointed to the fact that the deposits were not going down and claimed that as the amount of money was not decreasing rates must be kept up. That was a statement only in a slightly exaggerated form of the basis of the discount rate policy of the Bank of England, which looked much too much at the static position, at the reserves, as compared with deposits, and at the absolute level of the rate of exchange. If the Bank took account of the volume of

inactive deposits they might deal with the situation differently. Sir Henry Strakosch had criticised the fundamental premises of the whole of the argument with regard to interest rates by suggesting that too much attention had been paid to the effect of interest rates. Sir Henry approached the subject mainly from the commodity side and there was a great deal in what he said—accumulation of goods, no buyers, and a slump. But those who believed in the efficacy of interest rates thought that both on the rise and fall of prices a change in the rate made a good deal of difference. The press and economic literature during the recent boom suggested a scarcity of commodities right up to the slump, but as soon as the slump came it was discovered that everybody had been accumulating goods because prices were continually rising and people expected to profit. If the rate of interest was raised the cost of carrying the goods became greater, and it had some effect. During the slump if interest rates were greatly reduced it would tempt those who were inclined to be bulls and accumulate commodities, and at such times bulls were desirable. The danger now was not a superfluity of goods but a future shortage. Mr. Cecil Brown had referred to the question of the gold in America, which was a very difficult problem. America said she did not want inflation, that she had a tremendous stock of gold, and that to prevent her people using it she would keep interest rates up. If the only way in which credit based on that gold could be used was for internal purposes there was a good deal of reason in the argument, but it was correct to say that if on the basis of that gold they were to grant foreign credits there would not be an equivalent rise in internal prices. The American difficulty arose from their inability as much as their unwillingness to grant foreign credit, an inability due to lack of familiarity with that business. He was glad Mr. Marks had supported his appeal for a fresh Currency Committee because he attached a great deal of importance to it. Mr. Kipp thought it would be a great mistake to have such a Committee because Committees were always failures. If the Cunliffe Committee was a failure—as he thought it was—it was one of the strongest reasons for having another one which could not make the position worse and might make it better. The report of the Cunliffe Committee was said to be the bible of the Bank of England, and there was the chance that another Committee might induce the Bank to change its religion. If he had understood Mr. Simpson correctly, one of his main points of criticism was that the paper condemned the Bank for basing its policy on pre-war custom and theory, but at the same time asked the Bank to use its discount rate policy in the way in which it was used before the war. Mr. Simpson imputed to him a wish which was not his, for he should criticise the use of the dis-

count rate policy by the Bank as he criticised its use now. The use of the rate before the war was more successful because while the country was on a gold basis and conditions were more stable the rule of thumb adopted by the Bank led them, as he thought accidentally, more or less along the right track. They looked at the wrong things but those things led them right. To-day they looked at reserves and reserves had become useless as a criterion and they looked at the exchanges and no one knew what the real parity was. He believed that if the dollar rate was above 4 and rising it was a very good reason for having lower rates in London than in New York.

THE CHAIRMAN, in proposing a vote of thanks to the lecturer, said Mr. Falk had been somewhat disappointed that he did not give him anything to catch hold of—but that was his object; he did not intend to be drawn to do battle on the present occasion. He was sure everyone had learned a good deal from the paper and discussion in regard to such an interesting question. He thought that if Mr. Falk were a member of the Court of the Bank of England he would find that he attributed to the Members of that Court a great many sins for which they were not really responsible and a great many ideas and decisions of which really they were entirely innocent.

The motion was carried unanimously

A vote of thanks to the Chairman concluded the meeting

CHEMICAL RESEARCH FOR KEY INDUSTRIES IN INDIA.

In an article in a recent number of the Journal of "Indian Industries and Power," Mr. E. R. Watson, Principal, Research Institute, Cawnpore, points out the urgency of particular chemical researches most likely to lead to important industrial developments in India. In discussing this, he considers, first, a wider question, namely, what industries, involving chemistry, are most capable of development, or likely to develop in this country. The two problems are not synonymous, as there may be industries involving chemistry which are capable of large and successful development in this country, without the assistance of chemical research, or with very little assistance. Again, this second question, as to what industries, involving chemistry, are capable of development, is evidently part of a still wider question, viz., that of the industrial development of India as a whole.

GOVERNMENT'S WORK.

The chief contributions which have already been made to this subject should first be mentioned. The United Provinces Government

was early in the field, as in 1907 it considered the establishment of a technical institute at Cawnpore, of which one of the main functions was to be an investigation as to what chemical researches were most urgently required and most likely to be useful. It is satisfactory to note that the institute has now materialised.

The Industrial Commission's report (1913) has a chapter on the deficiencies in Indian industries. It points out the order in which industries have developed in other countries, viz., iron and steel manufacture first, then the production of textiles and similar goods by machinery, then the manufacture of chemicals required in these large scale industries. It also draws attention to India's deficiency in iron and steel production which has retarded the proper development of many industries dependent on machinery.

Drs. Sudborough and Somonsen have discussed chemical industries in the late Indian Munitions Board's Industrial Handbook (1919.) They there laid down the general principle that in any attempts to foster the development of chemical industries in India, attention should be directed, in the first instance, to industries which make use of the Indian-grown raw material now exported to other countries. Included in these exports are (1) the raw materials from which important fixed oils and feeding cakes are manufactured; (2) the raw materials from which valuable essential oils and medicinal drugs are prepared, and (3) various mineral products, such as chrome, manganese and zinc ores, wolfram and monazite sands. It is, however, admitted that the proposition of making India an oil and oil products exporting, rather than an oil seeds exporting, country, is not a simple one. In addition to industries, it is recognised that the manufacture of heavy chemicals is a key industry or group of key industries; and, as to their prospects, it is considered, firstly, that the manufacture of sulphuric acid for some time to come can be suitably obtained from Indian nitre (the utilisation of atmospheric nitrogen is considered to be a proposition requiring careful consideration), and, thirdly, that it is doubtful whether sufficient soda to meet all Indian requirements can be obtained by the extraction of alkaline soils. The cost of the ammonia soda process would probably be too heavy to permit of soda manufactured by this process competing with imported carbonate in normal times. The electrolytic production of caustic soda and soda ash could only be made a success by utilising the by-products, and Magadi soda is likely to be a dangerous competitor with the Indian manufactured article; but, nevertheless, alkalis are so important that it may be necessary to protect their manufacture. It is considered essential to manufacture chlorine and bleaching powder in India.

As to manufacture of explosives, synthetic dyes, drugs, etc., from coal-tar, it is considered

that the amounts of tar available in India at present are quite insufficient to start a large coal-tar industry, and that the only way to start such an industry would be to coke all suitable coal at the pit head.

The manufacture of permanganates, chromates and lead products, such as litharge, red lead, and white lead, are all considered to be eminently practical propositions.

Wood distillation is regarded as rather a doubtful proposition, owing to the existence of large supplies of its products and the low prices likely to prevail for some time after the war.

The Indian Munitions Board held a conference of chemists in 1918, and organised, as far as possible, chemical research work on industrial problems. Their list of chemical researches which have been taken up, includes very little under the head of heavy chemicals; it includes a good many researches on Indian oils, such as neem, mahva, til, fish oils, the hardening of oils, the manufacture of glycerine and varnishes, the utilisation of new Indian tanning materials and preparation of tanning extracts; the preparation and refining of essential oils, such as rose, patchouli, retivert, lemon-grass, clove, cardamom; the manufacture of strychnine, atropine and caffeine, the manufacture of chromates, wood distillation, and various problems which are not touched on in the chemical industries article in the handbook, such as the manufacture of starch, alcohol and glue.

The Chemical Services Committee (1919-20), have expressed the opinion that India is deficient at present in raw materials for the production of organic chemicals from coal, but consider that there is an enormous field for the production of carbon compounds from vegetable products. They explain that they do not only refer to such products as oils from oil-seeds, indigenous dyes, drugs and essential oils, but consider that there is a great field for the production of new products of greater economic value by the conversion of organic compounds present in Indian plants.

SULPHURIC ACID.

Owing to the importance both of sulphuric acid and zinc, the Government of India is interesting itself in the proposal to erect zinc-smelting works at Jamshedpur, where the zinc concentrates from Bawdin in Burma will be dealt with, and the spelter and sulphuric acid yielded made available to the Tata Iron and Steel Company for their own purposes and for subsidiary companies. The plant, which it is proposed to erect, with a loan from Government, will be capable of dealing with 25,000 tons of zinc concentrates, and the estimated output is 10,000 tons of spelter per annum, and 32,000 tons of sulphuric acid. The iron and steel industry requires large quantities of sulphuric acid for recovering

ammonia from the coking plant, and for pickling iron palte for galvanising and tinning. Most countries consume very large quantities in the manufacture of superphosphates. There is no reason to fear that the production of sulphuric acid will exceed the demand, but it should meet all requirements for some time, including requirements for the manufacture of explosives and dyes.

NITRIC ACID.

At present, India exports about 26,000 tons of nitre, consumes about 4,000 tons, and imports about 1,700 tons of Chili saltpetre. Her imports of nitric acid are negligible. With a sufficient supply of sulphuric acid there will be no difficulty about producing the nitric acid required for explosives and dyes.

CAUSTIC SODA.

The quantity of alkalis required for the manufacture of dyes and explosives, is comparatively small, and India's requirements in this respect could easily be met from the salts contained in alkaline soils. That it is a key industry there can be no question. The present consumption of alkalis is comparatively small (35,000 tons of soda imported in 1917-18), but increased production of cotton goods and soap is bound to multiply many times the present demand for alkalis. An increased demand for cotton goods is one of the most certain results of India's development, and with an increase in the production of iron and steel machinery, there is no doubt that increasing quantities of cotton goods will be manufactured in this country. The present value of cotton goods consumed per head of the population is Rs 2-12 per annum. There can be no doubt that this will be multiplied several times in the near future, and that the bulk of the goods will be manufactured in this country. This will increase proportionately the demand for alkalis, which are used for scouring cotton goods.

ALCOHOL.

As India is essentially an agricultural country, and exports large quantities of material such as grain, which are used in the country of destination for the production of alcohol, there seems no reason to doubt that industrial alcohol could be successfully produced in India.

Problems are certain to arise from the fact that the materials available, or climatic conditions or other factors, are different from those in the countries already carrying on the manufactures referred to above. These are platitudes which the British find hard to recognise, but which are, nevertheless, recognised to a greater extent than before the war. Apart from the fundamental industries there are others which are not, perhaps, of such vital importance. In others, there are any number of chemical problems appealing, perhaps, more strongly to the chemist, whose interests are primarily

scientific, e.g., lac-dye is thrown away at the present time. Again, in Indian turpentine we have a cheap source of pinene in any quantity. The chemical relationship between the different members of the terpene group is very close, and it seems quite feasible to convert pinene into the unsaturated open chain compounds.

THE CULTIVATION OF TOBACCO IN JAVA.

Tobacco is cultivated in Java (1) by natives working independently of foreign supervision; (2) by natives under the supervision of European companies; (3) by European planters, who lease the land from the natives, hiring them to work; and (4) by European companies who lease large tracts of land from the sultans and princes. According to a report by the United States Trade Commissioner in Java, the cultivation of tobacco by the natives of Java, like most of the native agricultural effort, is carried on with no conscious effort to improve the quality of the produce, the consensus of opinion being that such differences in quality as exist in the native production are due to the influences of the climate and soil. The cultivation of tobacco under the supervision of Europeans is centred in the residency of Bezuki, in eastern Java, and in the Vorstenlanden, which includes the principalities of Jokjokarta and Surakarta in the southern part of central Java. While the general process of cultivation is the same in both districts, the conditions of climate, soil, labour, and land tenure are not the same, and the product is of different qualities, although both find a ready sale in European markets.

The preparation of the soil for the cultivation of tobacco begins in April, as soon as the rice crop is off, and the land is turned back to the natives by January 1st. The tobacco companies in the Vorstenlanden, who lease the land from the sultans and princes, receive a rebate on their rental if they turn the land back before that date, and are subject to a heavy fine if they hold it longer. The rotation of crops includes one crop of tobacco from April to December, and three rice crops, requiring from four to five months to mature, making 24 months in all. In Bezuki three crops of rice are not usually possible, and one crop of maize or beans is substituted.

In the official customs returns for 1916 and 1918 the exports of tobacco from Java are listed under three grades, as follows: (1) Leaf tobacco, which is grown only by the estates under European control, is either consigned to the estates' agents in the Netherlands or sold direct by the estates. American buyers visit the principal centres yearly to make selections of this variety, the "American assortment" containing only the largest leaves of fine texture and light colour. (2) "Krossak," or scrubs, is leaf tobacco of grades lower than wrapper tobaccos. It is mostly of native cultivation

and is graded very exactly according to size, texture and colour. (3) "Gekorven" is a stripped and cut tobacco, made up of leaves that will not go into the "krossak" grades to good advantage, but are of fairly good quality. There is considerable labour attached to its preparation, which accounts for the higher price at which it is appraised by the customs. It is used by the natives, and when exported goes either to the Netherlands or to the near-by countries.

Within these grades there are many subdivisions, so that there are literally hundreds of grades known to the buyers. The above grades are qualified, as a whole, by the district in which they are grown, the principal varieties being the undermentioned.

Madura tobacco, which is grown on an island of the same name east of Java, stands as high as any in the "krossak" grades. The superior quality is due to climatic and soil conditions. During the past few years it has brought better prices than formerly, as some of its grades are desirable for the manufacture of cigarettes.

Bezuki tobacco is among the best of the scrubs. Besides the native cultivation there are large estates under European control which produce the finer types of leaf tobacco.

Loemadjang tobacco takes the name of a town in the eastern part of the residency of Pasuruan at the foot of the south-eastern slope of Smeru Mountain. The quality of the tobacco raised here ranks with that of Madura and the lower grades of Bezuki.

Malang tobacco comes from the district lying east of Smeru Mountain, the centre of which is the town of Malang. The elevation of this land is somewhat high and the quality is poorer than the above named tobaccos, which is undoubtedly partly due to climatic differences.

Kediri tobacco is grown on the lower stretches of the Kloet and Willis Mountains. It ranks with Malang tobacco, among the poorest of the scrubs.

Rembang tobacco is grown in almost every part of the residency of that name. The bulk of the "krossak" going through the Soerabaya market comes from this district, and it is of the lowest grade.

Kedu tobacco, grown in the residency of Kedu, is of a quality between that of the first-named group of those of Rembang, Kerdii, and Malang. The better grade produced here is attributed to a favourable climate and soil and to better seed being used.

Soerabaya is the principal tobacco market for Java. Much of the tobacco is drawn to this port by the superior warehousing facilities and by the speculator market. The port also has advantages in transportation over the port of Samarang in handling the tobacco from Kediri, Malang, Loemadjang, Bezuki, Madura, and ports of Rembang, although tobacco is often shipped from the minor ports. Cheribon, on the north coast of Java, ships only

"gekorven" tobacco from the Kedu district or from the small native culture in scattered patches throughout the vicinity of that port. Samarang is the port for tobacco from Kedu, the Vorstendlanden, and for a considerable part of the Rembang product.

The principal tobacco district of the Dutch East Indies is situated in the East Coast Residency of Sumatra and its product is shipped principally from Belawan Deli, Medan's port, and from Tanjong Poera, Tanjong Bali, and Tanjong Tirem, secondary ports handling considerable quantities of tobacco in normal years.

Tanjong Priok, Batavia's port, is the port of export of a large part of the tobacco from southern and south-western Sumatra as well as from the Palembang district in south-eastern Sumatra. Sumatra tobacco is distinct from Java-tobacco in quality and in the conditions surrounding its growth and marketing.

Before the war the Netherlands practically enjoyed a monopoly of the tobacco business of this colony, (Germany, Singapore, Penang, and Hongkong being the only other countries listed as purchasers in 1913, and, in the case of Java tobacco, only for small amounts. American purchases were then made in the Netherlands, but the scarcity of tonnage and marine risks brought the market to the Dutch East Indies in 1917. Shipments to the United States in this year consisted of approximately 500 tons of Java wrapper leaf, 85 tons of Java "krossak" and 1,215 tons of Sumatra wrapper leaf, while in 1918 the shipments amounted to 400 tons of Java wrapper leaf, 108 tons of Java "krossak" and nearly 1,900 tons of Sumatra wrapper leaf. Figures of export for 1918 showed a general purchasing in this market from abroad.

As is the case with the sugar planters, the tobacco planters of Java believe the time to be near when they will be forced to use machinery. Experiments have been made with a small tractor of the wheel type, but it was found to be too small and otherwise unfitted for the work. A small tractor of the caterpillar type was also to be tested. The efforts of the Sugar Syndicate to get a suitable machine for use in sugar cultivation are being closely watched. Success will undoubtedly have an influence on the plans of the tobacco planters.

While the problem in the tobacco fields is similar in some respects to that of the sugar planters, there are fundamental differences. The sugar planters have skilled mechanics and repair shops connected with their industry, while the tobacco planters have not. The sugar planters level the rice fields before planting, while the tobacco planters, especially in the Vorstendlanden, endeavour to preserve the contour, at least, of the rice fields. Sugar is planted in deep furrows from 4 to 5 feet wide and there is no series of successive ploughings, while the tobacco fields go through a slow preparation

for months before planting. The cultivation of tobacco requires light machines for the finer cultivation and yet the ground must be turned to a depth of 15 inches and some heavy ditching must be done.

It is suggested by the Trade Commissioner that manufacturers can assist the sugar and tobacco planters in solving their problems by sending drawings, illustrations, and prices of their machines to the proof stations, thus hastening the opening of a large market.

SOUTH INDIAN WATTLES.

By KALYAN C. SRINIVASAN, M.A., F.C.S.

Consulting Glue Chemist, Department of Industries, Madras.

Read before the Indian Science Congress on 3rd February, 1922).

The luxuriant growth of a species of black wattle in the high ranges and on the Nilghiris suggested the present investigation as to whether the areas would afford a valuable source of tannin, suitable either for local consumption or for export.

This paper summarises the results of an investigation of the tannin content, optimum temperature of extraction and tanning properties of the bark of *Acacia Decurrens* found in South India, indicates how the tannin content varies with age, and discusses the question of the wattle extract industry in relation to wood distillation in South India.

PRELIMINARY EXPERIMENTS.

Analyses of a few samples of air dried bark from full-grown trees were made in accordance with the hide power method of the International Association of Leather Trades Chemists, and as worked under Indian conditions by Mr Pilgrim, Tannin Expert to the Government of India.

Except in the case of a single sample of white bark (probably *Acacia dealbata*), which gave poor results, the analyses of South Indian wattles compare very favourably with those of other countries.

ANALYSES.

	Tans.	Non-Tans.
S. Indian ((Nilghiria)	39.3 to 42.1	7.3 to 10.3
„ (High Ranges)	40.1 to 44.1	7.1 to 13.0
Natal	35.2 to 39.8	7.3 to 10.3
Cape	40.1 to 44.1	7.1 to 13.0
East Africa 11	36.7 to 42.1	9.4 to 12.7
Australia	38.3 to 49.5	4.4 to 9.4
South Australia	40.2 to 49.5	9.0 to 9.4

OPTIMUM TEMPERATURE OF EXTRACT.

The tannin from South Indian wattle barks is easily extracted and has no tendency to form phlobaphenes on the filter candles. Experiments with a five-year-old bark from the High Ranges gave the following results:—

	Tans.	Non-tans.
About 32.°C. ...	15.1	5.3
About 65.°C. ...	28.2	6.1
Boiling water 100° C.	29.1	8.0

The optimum temperature is evidently somewhere about 60.°C. when the proportion of non-tans to tans is about the smallest and most of the tannin is also extracted.

TANNIN VARIATION WITH AGE.

This investigation was suggested by Mr Alan Guthrie, M.B.E., Deputy Comptroller of Hides and Principal, Leather Trades' School, Madras, and the samples were kindly furnished by him.

[Analyses are here given of barks from branches of trees of one, two, three, four, and five years of age, showing that the percentage of tannins in them is 18.37, 24.37, 25.97, 27.62, and 29.07, respectively.]

It is very clear from the above figures that the value of the bark increases with age. Not only the tannin increases, but the proportion between non-tans and tans decreases. This latter quality is necessary for the production of a valuable extract. It was also found that the thicker bark is richer in tannin than the thinner.

In the Transvaal the maximum tannin content is said to be found in the barks of trees from six to eight years old, while in East Africa, a high percentage of tannin in four-year growths is an important feature. Exudations of gum from South Indian Wattles might account for lower percentage of tannin, but the gum itself is valued at about £1 10s. per cwt. Work has still to be done using the bark of more mature growths of high range wattles.

TANNING TRIALS

With calf skins, a full soft leather was obtained. The leather when dried in the shade had a soft reddish tinge, a tint deeper than that obtained with *Auriculata* tannage, and on exposure to light, darkened visibly. The feel of the leather was very good and the leather itself betrayed no tendency to crack. The penetration of the tannin was nearly as quick as of the turved bark and is confirmed by the work of Coomba Alcock and Stelling (*Chemical Industry*, Vol. 36, page 190), who say that the wattle tannages compare very favourably with those of Mangrove, the tensile tests of the former running up to 3,200 lbs. per square inch.

UTILISATION OF SPENT BARK.

Laboratory experiments on a small scale on the spent bark of the high range wattles showed the possibility of producing about 30 per cent. of good pulp with fine felting quantities, readily bleached by S.O_2 to a pleasing ash colour. It may perhaps be possible to bleach it to a clean white, but this was not attempted.

It is reported in *Chemical Industry*, Vol. 15, page 499, that spent bark contains 41.2 per cent. of cellulose, and that the length of the fibre is about 1.2 mm. But the ultimate fibres in the samples of pulp obtained above were not more than 0.8 inches in length. At any rate, very satisfactory wrapping paper of excellent quality may be made out of the pulp.

UTILISATION OF WOOD.

The wood of the wattle tree is said to yield about 61 per cent. of cellulose and 50 per cent. of pulp capable of being used for the manufacture of straw-board.

The destructive distillation of South Indian wattle has given during semi-large trials in the Indian Institute of Science most promising results (see *Journal of the Institute*), heading the list of the South Indian woods for the value of its by-products

East African wattle gives:—

Charcoal	27.3%
Umde Pyroligneous Acid	48.3%
Acetic Acid	4.7%
Methyl Alcohol	1.21%
Acetone	0.24%
Dissolved Tar	5.7%
Separated	6.0%

(See Bulletin Imperial Institute, 1918, page 571.)

The ash on burning wattle is also very valuable as the following analysis shows:—

Moisture	9.80%
Combined H ₂ O	3.61%
K ₂ CO ₃	8.77%
Na ₂ CO ₃	2.10%
CaCO ₃	77.50%
Ca ₃ (PO ₄)	4.60%

CONCLUSION.

It will be evident from the foregoing that with the exploitation of the high ranges and the Nilghiris to their fullest extent, and the scientific plantation of most valuable species of wattles, the foundations may be laid in the near future for at least two important industries, that of the manufacture of tannin extracts and of wood distillation.

GENERAL NOTES.

HENRY SAXON SNELL PRIZE.—The Henry Saxon Snell Prize was founded to encourage improvements in the construction or adaptation of sanitary appliances, and is to be awarded by the Council of The Royal Sanitary Institute at intervals of three years, the funds being provided by the legacy left by the late Henry Saxon Snell. The Prize in the year 1922 will consist of Fifty Guineas and the Medal of the Institute, and is offered for an Essay on "Improvements in the Sanitary Appliances and Fittings for new Housing Schemes, having

regard to Efficiency and Economy." Essays must be delivered on or before August 31st, 1922, addressed to the Secretary of The Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W. 1, from whom further particulars may be obtained.

TRADE CONDITIONS IN AMRITSAR.—The United States Trade Commissioner in India writes that Amritsar, in the Punjab, with a population of about 150,000, is one of the wealthiest cities in north-western India. It is the centre for trade with central and western Asia, and offers much business opportunity, as many trade inquiries originate there. At one time there were 4,000 looms devoted to weaving Pashmina shawls, but with the decline of this business, carpet and rug making is now the most important single commercial industry. As the centre of the Sikh religion, many pilgrims go to the city annually, visiting also the numerous bazaars which are filled with all kinds of goods. While the quantity of foreign goods appearing in the stalls of these bazaars is not as great as is found in other places, such as the neighbouring city of Lahore, a certain amount is carried in stock. One of the noticeable features of this community is the extensive wearing of shoes and woollen clothes, owing to the cold winter climate.

ELECTRIFICATION OF NORWEGIAN RAILWAYS.—The Board of the Norwegian Engineers' Union has appointed a committee to investigate whether the time has come for electrifying Norwegian railways and whether the railways now being planned should be constructed for electric power, according to information furnished by the United States Commercial Attaché at Copenhagen.

INSULATOR TESTING IN FINLAND.—According to the United States Consul at Helsingfors, the Arabia Porslinsfabrik A/B, of that city, has installed a testing department with a capacity of 300,000 volts for testing high-tension material. It was built by the Allmanna Elektriska A/B in Finland, and is said to be the only one in northern Europe where tests can be effected with such a high voltage. The Arabia Co. has made insulators for the past twenty years, but not hitherto for such high tensions as are now required.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 p.m. (unless otherwise announced):—

APRIL 26.—JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E., "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application to the Jute Industry." SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the chair.

MAY 3.—NOEL HEATON, B.Sc., "The Production of Titanium Oxide, and its use as a Paint Material."

MAY 10.—MAJOR PERCY A. MACMAHON, R.A., LL.D., ScD., F.R.S., "The Design of Repeating Patterns for Decorative Work." SIR CHARLES CARRICK ALLOM in the chair.

MAY 24.—GEORGE FLETCHER, Department of Agriculture and Technical Instruction for Ireland, "The Natural Power Resources of Ireland."

MAY 31 (at 4.30 p.m.)—LAWRENCE HAWARD, M.A., Curator of the City Art Gallery, Manchester, "The Manchester Art Gallery and the Problem of Provincial Collections."

INDIAN SECTION.

Friday afternoons at 4.30 o'clock:—

APRIL 28.—F. G. ROYAL—DAWSON, M.Inst.C.E., "The Need for an All-India Gauge Policy." SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the chair.

MAY 26.—SIR THOMAS W. ARNOLD, C.I.E., D.Litt., M.A., Professor of Arabic, School of Oriental Studies. (Sir George Birdwood Memorial Lecture.) "Indian Painting and Muhammadan Culture."

Date to be hereafter announced:—

J. T. MARTEN, I.C.S., M.A., "The Indian Census."

DOMINIONS AND COLONIES SECTION.

FRIDAY, JUNE 9, at 4.30 p.m.—MAJOR SIR HUMPHREY LEGGETT, D.S.O., R.E., "Tanganyika Territory (formerly German East Africa)."

DOMINIONS AND COLONIES AND INDIAN SECTIONS.

(JOINT MEETING.)

Friday afternoon, at 4.30 o'clock:—

MAY 5.—PROFESSOR WILLIAM HENRY ECCLES, D.Sc. (London), F.R.S., Vice-Chairman of the Wireless Telegraphy Commission, "Imperial Wireless Communication." VISCOUNT BURNHAM, C.H., in the chair.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, APRIL 24. Building Trades Exhibition, Olympia, W., 6 p.m. Prof. P. Abercrombie, "What we Mean by Town Planning." Electrical Engineers, Institution of (Sub Centre), The University, Liverpool, 7 p.m. Mechanical Engineers, Institution of, Storey's Gate, S.W., 7 p.m. (Graduates Section). Mr. B. A. C. Hills, "Jigs and Tools."

TUESDAY, APRIL 25. Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m.

Textile Institute, 16, St. Mary's Parsonage, Manchester. Annual General Meeting.

Photographic Society, 35, Russell Square, W.C., 7 p.m. Technical Meeting.

Colonial Institute, Victoria Hotel, Northumberland Avenue, W.C., 4 p.m. Dr. H. A. Tempary, "Mauritius of To-day."

Zoological Society, Inner Circle, Regent's Park, N.W., 5.30 p.m. 1. The Secretary. Report on the Additions to the Society's Menagerie during the month of March, 1922. 2. Mr. R. J. Ortlepp, "A New Species of the Nematode (*Esophagostomum* from the Rodent *Xerus setosus*)." 3. Dr. C. F. Sonntag, "On the Anatomy of the Drill (*Mandillus leucophaeus*)." 4. Dr. R. Broom, "On the Persistence of the Mesopterygoid in certain Reptilian Skulls." 5. Mr. A. Loveridge, "New Reptiles from Tanganyika Territory."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. Sir Arthur Keith, "Racial Problems of Africa." (Lecture I.)

WEDNESDAY, APRIL 26. People's League of Health, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m.

Building Trades Exhibition, Olympia, W., 6 p.m. Sir Lawrence Weaver, "Modern Domestic Architecture: Fashion and Style."

Electrical Engineers, Institution of (S. Midland Centre), The University, Birmingham, 7 p.m. (N. Midland Centre), Hotel Metropole, Leeds, 7 p.m. Annual General Meeting. (N. Western Centre), 17, Albert Square, Manchester, 7 p.m. Annual General Meeting.

Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5 p.m.

Royal Institution, Albemarle Street, W., 3 p.m. Prof. D. H. MacGregor, "Industrial Relationships." (Lecture I.)

THURSDAY, APRIL 27. Illuminating Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m. Discussion on the Use of Light in Hospitals.

Optical Society, at the Imperial College of Science and Technology, South Kensington, S.W., 7.30 p.m. Prof. A. Pollard, "The Mechanical Construction of the Microscope from a Historical Standpoint."

Royal Institution, Albemarle Street, W., 3 p.m. Prof. E. H. Barton, "The Resonance Theory of Audition." (Lecture I.)

Child Study, Society of, 90, Buckingham Palace Road, S.W., 6 p.m. Dr. Octavia Lewin, "The Natural Defences of the Upper Air Passages."

Electrical Engineers, Institution of, and Electro-therapeutic Section of the Royal Society of Medicine and the Röntgen Society (Joint Meeting), Savoy Place, Victoria Embankment, W.C., 6 p.m.

Concrete Institute, 296, Vauxhall Bridge Road, S.W., 7.30 p.m. Mr. W. N. Twelvetrees, "Reinforced Concrete Piers and Marine Works."

FRIDAY, APRIL 28. Royal Institution, Albemarle Street, W., 9 p.m. Dr. A. Harden, "Vitamin Problems."

Electrical Engineers, Institution of (Scottish Centre), Technical Institute, Dundee, 7 p.m. Dr. S. P. Smith, "Single and Three-phase Commutator Motors, with Shunt and Series Characteristics."

Physical Society, Imperial College of Science and Technology, South Kensington, S.W., 5 p.m.

Marine Engineers, Institute of, 85, The Minories, E., 6 p.m. Annual Meeting.

Aeronautical Engineers, Institution of, at the Engineers' Club, Coventry Street, W., 6 p.m. Capt. Sayers, "Some Unsettled Problems of Aeroplanes Design."

Engineers, Junior, Institution of, Caxton Hall, Westminster, S.W., 8 p.m. Capt. H. Whitaker, "Some Notes on the Utilisation of Water Power."

Mechanical Engineers, Institution of, Storey's Gate, S.W., 6 p.m. Prof. E. G. Coker, and Dr. K. C. Chakko, "An Account of Some Experiments in the Action of Cutting Tools."

*Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday morning of the week preceding the Meeting.

*For Meetings of the ROYAL SOCIETY OF ARTS, see page 395.

VOL. LXX.

FRIDAY, APRIL 28, 1922.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, MAY 3rd, at 8 p.m. (Ordinary Meeting). NOEL HEATON, B.Sc., "The Production of Titanium Oxide and its Use as a Paint Material." ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, in the Chair.

FRIDAY, MAY 5th, at 4.30 p.m. (Joint Meeting of Dominions and Colonies and Indian Sections). PROFESSOR W. H. ECCLES, D.Sc., F.R.S., Vice-Chairman of the Wireless Telegraphy Commission, "Imperial Wireless Communication." THE RIGHT HON. VISCOUNT BURNHAM, C.H., Chairman of the Empire Press Union, in the Chair.

INDIAN SECTION.

The Council have appointed Lord Montagu of Beaulieu, K.C.I.E., C.S.I., a member of the Committee of the Indian Section.

PROCEEDINGS OF THE SOCIETY

INDIAN SECTION.

FRIDAY, MARCH 24TH, 1922.

SIR THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., LL.D., D.Sc., F.R.S., in the chair.

THE CHAIRMAN said he would like to explain why he had accepted the Council's invitation to preside over the meeting. The problem of natural indigo in India came prominently to his notice when President of the Industrial Commission. The Commission spent some time in collecting evidence in the planting district of Bihar, and inspected the work being done by Mr. Davis and other agricultural chemists at the Pusa Institute. Some of the scientific questions involved came again to his notice in 1920, when, as a member of the Governor-

General's Council, he was temporarily responsible for the Department of Agriculture. It became obvious to the Industrial Commission that after the clearing of the political fumes which were still, at that time, hanging round Tirhoot, after the Champaran riots, among the most important of the influences likely to affect the issue of the great struggle between natural indigo and the synthetic product was chemistry, and that organic, agricultural and biological chemistry must play a predominant part in that struggle. By a rare chance, owing to the war, a chemist who had earned a world-wide reputation by his researches became inoculated with an interest in the scientific troubles of the indigo planters, and had now lent to the problem of natural indigo a fresh and original mind, working on a foundation of experience in questions connected with the development of the synthetic substitute which was almost unique. The meeting would listen to him that afternoon not as an advocate or even as an expert witness, but as a judge who knew both sides of the question.

The paper read was:—

THE INDIGO SITUATION IN INDIA.

BY PROFESSOR HENRY E. ARMSTRONG, PH.D., LL.D., D.Sc., F.R.S.

Vice-Chairman, Lawes Agricultural Trust Committee.

To-day I take up the story of Indigo which I began to tell to this Society on May 15th, 1919, describing work done by the Indigo Research Chemist, Mr. W. A. Davis, in Bihar, during the preceding three years. When the task was undertaken, I had in mind the composition of a triumphal march, not of a dirge; now I am overwhelmed by it and have difficulty in joining a just measure of joy with my grief. The pen of a Gibbon alone could write the oration proper to the funeral at which we are met—for such it is. The work is to be discontinued, though the inquiry has been most fruitful from the beginning and is of the greatest public consequence. I would

that the disease to which the patient succumbs could be diagnosed as the mere impecuniosity of the times: I fear it is far more grave and deep-seated—nothing short of general apathy and inability to appreciate the issues at stake, the need and value of acumen and understanding in agriculture. Yet agriculture, of all Indian industries, is beyond compare the most important; that in which considered, constant attention is most required. Indigo does not concern a few British planters alone: the problems underlying the successful cultivation of the plant are those of agriculture generally.

From time immemorial, the practice of all peoples apparently has been to grow a *leguminous* crop in alternation with a cereal or other non-leguminous plant; we have learnt, only in modern times, to appreciate its special function, that it is the means of bringing down nitrogen from the heavens into the earth; in addition, however, the leguminous plant has a peculiar value as an organic manure, especially under conditions such as prevail in Indian soils and in a country where animal faecal manure is not available. The dyestuff indigo is, therefore, little more than a by-product; the plant residue has a high agriculture value. Moreover, the yield of plant is necessarily affected by the condition and cultivation of the soil and the produce of other crops is more or less proportional to that of the leguminous crop in the rotation, because of the treatment the soil has received and of the contributions to the soil from the plant, both during its growth and as a green manure.

Much has been done to study the growth of cereal crops but we are extraordinarily behind in our knowledge of the conditions affecting leguminous crops. Even in the case of cereals, our studies have been mainly statistical, concerning as they do the yield of grain: we have little definite information as to the influence of conditions upon quality; in fact, are not yet agreed as to the criteria of quality. Still more is this the case with leguminous crops. In studying not merely the crop-yield but particularly its quality, as measured by its indigo-giving power, Mr. Davis has taken a step forward of the greatest possible consequence in agriculture, because of the importance of leguminous crops as food materials. We have reason to believe that the nutritional value of a crop is subject to considerable variation,

according to the conditions of growth; it is of utmost consequence that we should understand the manner in which such variation takes place, the more as leguminous seeds figure so largely in the Indian dietary. No other leguminous crop appears to afford the same opportunity as the indigo plant—no individual constituent can be singled out as a criterion of quality and estimated easily, as indoxyl the precursor of Indigo can be.

It is desirable to correct a misunderstanding, which seems to be current, that Mr. Davis was first appointed for a year to develop the manufacture of an indigo-paste which could be exported from India and only then appointed for a further period of five years to study the problems of indigo generally. As I was directly responsible for his appointment, I am in a position to place the facts upon record. When I recommended him and the terms of his agreement were under discussion, I was pressed to make it for five years; but I insisted that it should be only for a single probationary year. I was fully conversant with the unfortunate history of indigo; I knew that the problem was very complex and that success was not a question of mere practical and scientific ability but that the personal element would also count. When in Calcutta, in November, 1914, I had pointed out, in a letter to *The Statesman*, that it should be possible to effect improvements especially in agricultural practice, as well as in the plant itself and in the process of manufacture. I was anxious that Mr. Davis should have the opportunity of proving his fitness to undertake the great responsibility of the combined task.

The problem, *as a whole* and in all its parts, was assigned to him from the beginning; but he was advised, in the first instance, to prepare a paste comparable in form with that in which the Germans put synthetic indigotin upon the market, *i.e.*, a paste containing as nearly as possible 20% of indigotin. Incidentally, let me here again emphasise the fact that the Germans have never made *indigo*.

The immediate success of artificial madder (Alizarin), which preceded indigotin, was due almost entirely to the fact that it was supplied as a paste of definite strength; the same policy was at the root of the success of synthetic indigotin. Had the planters, when competition began, put indigo upon the market as a paste of standard strength,

I believe their industry would not have been ruined; indeed, in my letter to *The Statesman*, I wrote:—"If the advantage gained by natural indigo through the war is to be maintained, I believe it will be necessary for planters in future in some way to arrange to bulk their products and put upon the market a paste of fixed composition comparable with that supplied by the Germans."

At the same time, I expressed the opinion that it should be possible to secure a fair share of the trade for natural indigo in competition with the synthetic article. Now, I am prepared to affirm, with far greater emphasis, my belief in a secure future for indigo. Not only has it a markedly higher value, as a dyestuff, than indigotin pure and simple, but it may well happen that not a few natural dyestuffs may once more be in demand, because of the difficulty of obtaining the raw materials for the manufacture of artificial substitutes. I have long been a prophet of a time when, whatever the supply of cakes and ale, there will be little or no coal tar. We are rapidly losing patience with ourselves as smoke producers and bent on reforming our characters; even *The Times*, through the eloquent pen of Mr. Maurice Hewlett, has indulged in sun-worship of late; there are signs of our recovering this most ancient of cults by resort to smokeless fuels produced at low temperatures; a prominent representative of the most conservative of known industries has admitted this, only recently, on this platform, while smoking himself in illustration of the dangerous qualities of smoke.

But gas works are not the only source from which the raw materials of the dyestuff industry are supplied; a considerably larger quantity of coal than they use—perhaps twice as much—is carbonised at a high temperature in producing metallurgical coke, mainly for use in the blast furnace; much benzene, naphthalene, etc., is derived from this source. The probability is in no way remote, that changes may be introduced into iron smelting which will render the production of such coke at a high temperature unnecessary.

Should there be a shortage of the raw materials from which dyestuffs are now manufactured, natural colouring matters, especially indigo, will necessarily again come to the fore.

NATURAL INDIGO PASTE.

Two of the chief advantages which have always been claimed for synthetic indigotin in comparison with indigo are uniformity of colour-strength and fineness of division. It has been the custom of the makers to supply the synthetic product in the form of a paste containing 20% of dry indigotin; in this paste, the pigment is in so finely divided a state that no mechanical preparation is necessary to make it ready for dyeing or printing. Indigo may contain any proportion up to 75% of indigotin and must be subjected to a long and troublesome grinding process to render it fit for the dye-vat. Most dyers were glad to be relieved of the burden and I have heard it said, that the Germans hastened the abandonment by buying up the machinery.

On his arrival in India, Mr. Davis had no particular difficulty in removing water directly from the precipitated indigo to the extent required to give a paste containing as nearly as might be 20% of indigotin, leaving indigo-brown out of account. He was able to keep this from changing, even under Indian conditions, provided the paste were exposed to air; but on closing up the packages, anaerobic organisms became active; apparently, even these could be kept under by an increased dose of alkali. Several casks of the paste were sent to England. When these were opened in my presence, slight gaseous pressure was manifest and a slight faecal smell, showing that the organisms were not entirely thrown out of action. Analyses seemed to show that the paste was a unit or so below 20% strength. I may here say that the results returned by the different analysts were discrepant and it is clear that the methods of analysis commonly practised need careful revision. The paste was submitted to several competent dyers and declared excellent.

Satisfactory as was this trial on the whole, it was obvious that to send a paste which was mainly water all the way from India, could scarcely be an economic proceeding; soon, however, owing to the war, it became difficult, if not impossible, to procure casks or other suitable packages; later on, even cake indigo could rarely be shipped.

We therefore determined to continue the inquiry here and endeavour to make a paste from cake indigo, so as to gain ex-

perience and to avoid the sacrifice of opportunity. Fortunately, Mr. Reginald Brown was induced to undertake the task; great credit is due to him for the good work he has done and the proof he has furnished, that paste prepared from the natural material is not only equal but superior to synthetic indigotin for most dyeing purposes. It is only within the last three years, however, that the process has been made a commercial reality and success. The superiority is, I believe, due to a specific effect of indigo-brown in the dye-vat.

When the task was undertaken in earnest, the two chief difficulties encountered were the selection of suitable mechanical means of mixing and grinding and the preservation of the paste. Eventually, by grinding successively in machines of two different types, both used previously only in the preparation of pigment colours, even the hardest varieties of cake indigo (requiring at least a fortnight's grinding in the ball-mills formerly used) were converted, in the course of two or three hours, into a paste indistinguishable in fineness from synthetic indigotin paste, satisfying, in this respect, the most exacting demands of the dyer and even of the calico printer. The two pastes underwent reduction with equal ease both in the hydro-sulphite vat and in the zinc-lime vat.

To ensure that the paste shall keep has been a more difficult task. The incidence of bacterial action is very slight below 60° F. but trouble is experienced, at British summer temperatures, unless prevented by a suitable addition to the paste. The usual antiseptics are ruled out, as their presence might interfere with the course of useful processes in the "woad vat" or other fermentation vats (that this interference actually *does* take place has not been definitely established), though in paste to be used in the hydrosulphite or zinc-lime vat there is no objection to the presence of either phenol or formaldehyde.

From the trials made with a large number of substances, at a range of temperatures from 60° to 120° F., it appears that a small addition of paranitraniline (0.05% of the weight of the paste) retards bacterial change almost entirely and is without interference in the dyeing process; natural indigo paste containing this addition can be stored during many months in temperate climates without fear of deterioration. In tropical countries, however, the presence of parani-

traneline is insufficient to prevent all decomposition; evidently some highly resistant organisms are not destroyed by it. Experiments are, at present, in progress to adapt to the commercial scale another sterilisation method, which has been proved effective in the laboratory.

Natural indigo paste now has a ready sale in this country, the quantity being limited only by the supplies of cake indigo which the planters are able and willing to furnish at a price enabling the paste to be prepared and sold in competition with synthetic indigotin; this quantity has not been large, because the prices ruling in the Eastern market have been higher. The real market for indigo will probably always be in the East.

With regard to the dyeing properties of indigo paste, it is certainly superior to synthetic indigotin. To quote from a statement I made in *The Times* of April 8th, 1920:—

"Trials of a strictly scientific character have been made with piece goods, on a practical scale, by Messrs. George Garnett and Sons (of Apperley Bridge, near Bradford), a firm of great experience as indigo dyers. Vats were set and worked with equal proportions of natural and artificial paste; two pieces were dyed at a time, equal weights of cloth being taken for each vat. The number of comparisons thus made was 37, using 74 pieces of cloth. In each comparative trial the depth of shade produced was greater in the vat charged with natural paste. Mr. Reginald Brown estimates the superiority in depth in the series of dyeings at from 5 to 20 per cent. or an average of 12.5 per cent. The difference is patent even to my uninstructed eye. A serge properly dyed with indigo should always rank superior to one dyed with indigotin only."

I should add, in fairness, that synthetic indigotin is superior for light shades, especially in printing discharge patterns upon calico, as the whites are left clear and bright.

"The marked superiority of the natural product must be ascribed," I said, "to the presence of constituents other than the blue dyestuff indigotin, the sole constituent of the manufactured article. Indigo, in other words, is a material different from indigotin. The Germans are not to be credited with the production of indigo but only with having made its chief con-

stituent—a sufficiently notable achievement, however. It is not permissible, in fact, to speak of synthetic indigo; nor is it necessary to speak of indigo as natural indigo.”

Indigo dyed cloth has a peculiar bloom, a hue and tone which are distinctive: hence the preference in which it is held by those who are judges.

In concluding this section, I may add that in preliminary experiments, Mr. Davis has found that it is possible to air-dry indigo to an easily pulverulent form in which it requires practically no grinding. I believe this will ultimately prove to be the best form for export and one likely to satisfy all requirements if supplied of standard quality; until then indigo should be sent out as standardised paste.

THE MANUFACTURE OF INDIGO FROM THE JAVA PLANT.

In 1919, I dealt mainly with the agricultural problem, particularly the phosphatic depletion of Indian soils; nothing was said of the process of manufacture. Systematic work has been carried on since 1917, at Pusa, to elucidate this process, by Mr. Davis in collaboration with the Imperial Agricultural Bacteriologist, Mr. C. M. Hutchinson; considerable progress has been made, especially during the past season or two. In spite of much work by previous observers, practically nothing was known of the exact course of the process of extraction.

The dyestuff is not an immediate natural product. Its precursor in the leaf is the simpler substance, *Indoxyl*, C_8H_7ON , which is present in combination with the sugar, glucose, $C_6H_{12}O_6$, as the glucoside, $C_{14}H_{17}O_6N = C_8H_6ON.C_6H_{12}O_6$ *Indican*, which is easily soluble.

To produce indigo, it is necessary that the indican should be extracted from the leaf; that it should then undergo hydrolysis:

$C_{14}H_{17}O_6N + OH_2 = C_8H_7ON + C_6H_{12}O_6$; and that the indoxyl thus obtained should be converted into indigo by oxidation:

The plant is cut at daylight and carried as quickly as possible in carts to the factory, where it is packed in large cement-lined tanks; when the charging is complete, water is run in; then after several hours' steeping, the extract is run off into beating tanks, where the liquid is brought into contact with air and the indigo precipitated. As much of the liquid as possible having

been run off, the sludge is removed to filters and then to presses; finally, the press cakes are dried in the air.

Mr. Davis has discussed his earlier observations on the extraction process at length in Indigo Publication No. 9, published a year ago.

Two main problems are to be solved: first comes the nature of the process by which the leaf is rendered permeable, so that water can enter and the indican pass out into solution; and second, the process by which the hydrolysis is effected. A natural leaf is impervious. At the outset, a more or less vigorous bacterial fermentation is set up in the tank, doubtless at the expense of sugary materials exuded from the cut ends of the plant stalks and bruised leaves. The water used in Bihar is usually hard and alkaline. During the first three or four hours, little, if any, indican is extracted; then, as the solution becomes acid and acidity increases, more and more passes out and is usually hydrolysed forthwith. In Bihar the best results are obtained by stopping the steeping process after about 12 hours; if it be continued beyond the optimum period, destructive changes take place which involve both a loss of indigo and an increase of impurities in the product.

It would not have been a surprise had it been found that organic acids were formed by fermentative action during the earlier period. This is proved not to be the case; the development and increase of acidity is mainly due to carbonic acid. As this acid by itself acts but slowly upon leaves, although it ultimately renders them permeable, it is probable that the change at the leaf surface is due rather to a combination of circumstances leading to the death of the leaf and the onset of internal changes which involve complete degradation of the vital mechanism. Not only is carbonic acid formed but oxygen disappears from the solution; and the leaves are in the dark and immersed in water—all unnatural conditions. Nevertheless, weak as it is, carbonic acid demonstrably plays an extraordinary part in the process, the quality of indigo produced being the worse the more freely the acid is formed.

Previous workers have inclined to the belief that the indican is converted into indoxyl and glucose by the agency of an enzyme present in the leaf. Messrs. Davis and Hutchinson, however, have brought forward a body of evidence which the

former is inclined to interpret as proof that organisms play a preponderating part. Mr. Davis is even of opinion that the enzymic actions within the leaf are rather to be avoided, as they lead to undesirable results. When the extraction process is set going at the beginning of a season, usually the results are poor at first, the product being low in quantity and quality. The following data from records secured in 1916 are typical:—

	Sumatrana Plant.		Java Plant.
	Produce per 100 maunds.		
	Sr.	ch.	Sr.
1st day	..	0 5	7.4
2nd	..	1 2	10.1
3rd	..	7 1	6.0
4th	..	8 0	14.8
5th	..	Java Plant	12.8
6th	..		14.0
7th	..	11 6	16.0
8th	..	9 6	14.0
9th	..	12 2	steadily 14-16

Apparently during the earlier period the useful organisms are accumulating on the walls and cross-beams of the steeping tanks. Mr. Hutchinson has developed a method of cultivating the organisms which occur in the vats on plates of agar containing indican: organisms growing upon these which liberate indoxyl are easily distinguished by the blue colour of their colonies. Using this test, Mr. Davis has found extraordinary differences in the way in which the different organisms affect indican, both as regards the rate at which they determine its hydrolysis and the extent to which they exercise a destructive action.

An interesting opportunity was afforded him in 1919 at a small factory at Panchnoi, in Assam, where the manufacture was undertaken for the first time in Assam by Mr. Leo West. During the first month, in which, following the Bihar practice, steeping lasted 12 hours, the results were most irregular and unsatisfactory; only from 3 to 13 seers per maund were obtained of an indigo of low quality, containing from 31 to 53 per cent. of indigotin. The water used was found to be entirely different from that in Bihar, being very soft. When bacterial cultures were made by Mr. Hutchinson's indican-agar method, the water, as a rule, was proved to be extraordinarily deficient in indican-splitting organisms.

Mr. Davis further found that when the Panchnoi water was added to a sterilised

solution of indican, the production of blue indigo set in only after 36-40 hours, whereas, when ordinary Bihar water—well supplied with indican-splitting organisms—was used, a blue deposit of indigo was obtained within 12 hours. In carrying out the 23rd to the 29th extractions, during which period the results were most variable, it was noticed that, whereas on satisfactory days there was a good development of the indican-splitting organisms on the agar plates, this did not happen on the other days. The water was obtained from a small river rising in the hills a few miles away and evidently changed its bacterial character very rapidly as the rainfall in the hills varied. At the 33rd extraction it occurred to Mr. West to double its duration: a very high yield and greatly improved quality of indigo was then obtained and this condition continued regularly over 30 days in succession. In Bihar, if extraction be continued beyond 24 hours, the produce is very poor. The following example of results from a steeping vat will illustrate the rapidity with which deterioration sets in:—

Time of steeping	8 hrs.	11 hrs.	13 hrs.
Percentage of total indigotin of leaf found in extract	.. 45.4	83.0	56.6
Purity of crude indigo	.. 71.8	66.6	51.8

It will be seen that a loss of nearly two-thirds of the indigotin was incurred by two hours' over-steeping.

Mr. Davis was led by these observations to realise that it would be of great advantage to ascertain the optimum time of steeping under the particular conditions prevailing in each factory and ultimately to devise a simple time test. This involves nothing more than taking a sample every half-hour from the running-off pins or by means of a syphon from the bottom of the vat. Five cubic-centimetres of the sample are measured into a flask and after six to eight drops of strong ammonia diluted with five volumes of water have been added, the liquid is made up to 250 cc. and well shaken; finally it is poured into a 100 cc. Nessler cylinder. The successive samples are ranged in order and the depths of colour observed. So long as the extraction is incomplete, the depth of blue colour steadily increases; directly the blue colour begins to appear fainter, extraction should be stopped.

Using this test in Bihar, it is found that every half-hour counts: marked improvements in quality and constancy of product have been effected wherever the test has been introduced. It constitutes a great advance in the technique of the extraction process. Moreover, other improvements are likely to come in its train, as Mr. Davis has found by its use that, not only does the extract at different heights in the vat vary in strength but that the closeness with which the charge is packed is of consequence, as the proportion of potential indigotin dissolved out depends upon the ratio of water to plant.

To return to the problem of bacterial action, whilst it is clear that organisms play a determining part, it is not so clear what part the leaf enzymes take in the process; judging from the Panchnoi results, they do not seem to be specially active; it is difficult to understand the slowness of the extraction. Unfortunately, these experiments were not carried to the point of ascertaining to what extent the indican had been dissolved out of the leaf at different periods of steeping, nor to what extent it had been hydrolysed; the unsatisfactory results may have been due to a preponderance in the earlier stages of extraction of organisms having a destructive influence upon indoxyl. No proof has been given, moreover, that indican as such escapes to any extent from the leaf: the conclusion Mr. Davis draws from his results is that usually it is hydrolysed to indoxyl practically as fast as it is extracted from the leaf. Maybe the differences observed are all but entirely the outcome of competitive actions by the different organisms: until these are isolated and their individual effect established, it will be difficult to overlook the entire process.

Indoxyl is one of the most sensitive substances known to the chemist. It may exist in solution in two interconvertible forms, in proportions which vary probably with temperature and the effective alkalinity or acidity of the liquid. These may be differently affected by organisms and on oxidation. The results obtained in the beating vat vary as the acidity is varied and the most favourable results are obtained when the solution is neutral or faintly alkaline with ammonia. The main change in indoxyl is more fundamental: apparently derivatives of this compound are present in the liquor which are not convertible into indigo but into indigo-brown, the nature

of which is at present unknown; a considerable proportion—often a third—of the indican, however, is carried beyond this stage and for the loss of this we cannot fully account at present.

Carbonic acid may have an influence either by retarding or promoting the action of this or that organism; perhaps its main deleterious action is the solvent action it exercises upon proteinaceous substances present in the leaf, which are subsequently precipitated during the beating process, together with the indigo, thus reducing its purity. The so-called indigo-gluten, soluble in dilute acids, which may form 20 per cent. or more of the crude indigo, is formed in this way.

The process is a remarkable illustration of the manner in which untutored human ingenuity has solved most difficult practical problems in a manner which we cannot well surpass, even with the aid of our great scientific knowledge; at most we can explain their character and so contribute to more regular and successful working. This is the position of the indigo industry.

Whilst the process is one of extraordinary complexity—the mysteries whereof will not be unravelled nor the conflicting elements disentangled without much further labour, combined with the highest technical skill and acumen—the means employed are of striking simplicity: to devise an economic alternative treatment, comparable with it in efficiency, would be very difficult. No effort should be spared, therefore, to master its details, so that the manufacture of indigo may once for all be placed upon a scientific basis: more than a beginning has been made; if the undertaking be interrupted now, a great opportunity will have been sacrificed.

CONDITIONS AFFECTING YIELD OF PLANT AND OF INDIGO.

Three years ago I drew attention to the evidence Mr. Davis had obtained as to the effect of manurial treatment on the yield and *quality* of the plant: the latter being measured by its richness in *indican*. In the interval he has discussed the subject more fully in Indigo Publication No. 7, published in June, 1920, as well as in a report made in July last.

Systematic trials were begun at Pusa, in 1917, on 12 experimental plots, each one-quarter of an acre in area; on one of these a cover crop of wheat was grown,

together with the Java indigo plant, this latter being in lines two feet apart, the wheat in two rows eight inches apart and eight inches from the indigo plant on either side. The indigo seed was sown in the proportion of four seers, the wheat (Pusa No. 4) of one maund to the acre. The date of sowing was October 24th, 1917. The plot had lain fallow during the previous hot weather and had not been manured. Other plots were sown with indigo seed alone, also in lines two feet apart. The usual plan adopted by planters is to space the rows only six inches apart. Mr. Davis regards this as not only wasteful of seed but as the plant is crowded, when it grows it sheds leaf and has no chance to bush out the percentage of leaf is, therefore, low.

In both years the indigo plant grown together with wheat was very backward in comparison with that on other plots without wheat, up to and some time after the wheat was cut, being only one to two feet high instead of four to seven feet. In 1918, soon after the rain in June, however, the plant grew in a remarkable manner, and when first cut, at the end of July, the yield was greater than on the comparison plots, excepting that on which the indigo plant and wheat had been grown alternately (B10); the second cut was small. In 1919, owing to a very late monsoon, the first cut was small but the second cut made up the deficiency.

The results are given in detail in Tables I. and II. (See pages 417 and 418).

It will be seen that the plant grown together with wheat was extraordinarily rich in indican in comparison with that grown on other plots, even in the 1919 season, when the percentage of potential indigotin was relatively high in all the crops.

From analyses of many hundred samples of Java indigo leaf, cut at various times and grown under different manurial treatments, Mr. Davis has found that, at Pusa, the potential indigotin varies usually between 0.4 and 0.6 per cent.; values as high as 0.7 per cent. are unusual and he has never before found values so high as those obtained in these trials—from 0.8 to nearly 1 per cent. on B.9.

It is well known to planters that, on some estates, certain fields often yield a big crop but little indigo. In the early days of the use of seed as a manure, the indigo plant was frequently grown directly on seeded land but although the crop was

greatly increased, it was found that the quality was so much impaired that there was no increase in the amount of cake indigo produced per acre. The importance of this difference was specially noted by me in 1919.

When account is taken of the conditions at Pusa, the results are an indication, apparently, that the main cause influencing the production of indican is a low proportion of nitrogen in the soil. Mr. Davis is of opinion that the conclusion arrived at previously by Bergthell is correct—that the production of indican is a starvation phenomenon, with the limitation, however, that to obtain also a higher yield of plant the starvation must be restricted to nitrogen.

In point of fact, the yield of indigo in the trials under consideration was inversely proportional to the amount of nitrogen in the soils, as shown in the last column of Table II. In B.9 the nitrogen falls even below the amount present in most indigo soils of Bihar, which usually contain from 0.3 to 0.5%; the percentage in the other plots was considerably higher and nearly three times as great in B.16.

Whereas plot B.9, on which alone the indigo plant was grown together with wheat, containing 0.027 per cent. nitrogen, gave 130 maunds, 37 seers of plant, estimated to yield 47 seers of indigo, the plot richest in nitrogen, B.16, containing 0.076 per cent. (also phosphatically the richest), gave a large crop of 141 maunds 14 seers; yet the yield of indigo from this latter was estimated to be only 25.5 seers.

On contrasting the results of the three years 1918-20, it appears, moreover, that although the climatic conditions varied widely and also the yield of plant per acre, a steady and marked improvement has taken place each year in the quality of the plant—i.e. the proportion of potential indigotin—in soils which were either unmanured or treated with phosphate, in some cases the possible yield of indigo per 100 maunds of plant being nearly doubled. The results are summarised in Table III. (See page 419).

The only explanation which can well be given of this steady improvement is that it was due to the gradual elimination of readily available nitrogen. That there was such an elimination seems clear from the fact that on plot B.9 the yield of wheat has steadily and rapidly fallen from year to year, from 11 maunds per acre in 1918 to 2 maunds in 1921. In the season 1921 the results were still better.

TABLE I.
Yields and analyses of Java plant from Punjab experimental plots, 1918.

Each plot was $\frac{1}{2}$ acre. Returns are calculated on the acre.

			MOORHAN.*				KHOONTIES.				TOTAL FOR SEASON.

B. 16	Indigo continuously. No manure.	30th July, 1918.	102	36	42.5	13.2	28th September, 1918.	3	4	73.7	0.459	106	13.9	0.076---

NOTE 1. The analyses of the leaf were made by the Isatin method. The values given are the average of two closely concordant duplicate analyses.
 2. Plot No. 12 was sown in August, 1917, for seed. The seed was collected in March and early April, 1918, and the plant cut down to 6" and left to give a leaf crop, which is, therefore, the second leaf crop. This plot gave no Khoonties at all after the cutting in July. It failed to produce fresh leaf.
 3. The possible yield of 60 per cent. indigo is calculated as follows: for example, plot B. 9—103 mds. 28 srs. = 4,148 srs. Possible yield per acre—

$$\frac{4,148 \times 0.475 \times 0.807 \times 100}{100 \times 60} = 26.50 \text{ seers } 60 \text{ per cent indigo cake.}$$

From the manurial trials made at Pusa with super and sannai as green manure, it appears that on such soils this treatment not only gives a very high yield of indigo per acre but the quality of the plant is also high, though not quite so high as that of plant grown without manure. When the indigo plant is grown with the aid of indigo seet as manure, there is a big increase in growth of plant but no extra production of indigo. There is a marked difference in behaviour of the plant according as fresh green manure is used or the fermented indigo plant in the form of seet; fresh indigo seet apparently increases the growth of the plant only at a corresponding sacrifice of quality.

The lesson to be derived from the various trials undoubtedly is that it is necessary to ensure three conditions to secure maximum quantity of a high quality plant :—

1. A low proportion of readily available nitrogen in the soil.

2. A good supply of organic matter to furnish the necessary (?) carbohydrate nutriment on which the development of the nodular growths on the roots largely depends.

3. A good supply of soluble phosphate.

The leguminosæ are peculiar plants which

seem to lead a double life. They have acquired the habit and power of making slaves of bacterial organisms, which become housed in nodular growths upon their roots—these are the factories in which the assimilation of atmospheric nitrogen is effected. When the plant is grown in sterile soil, nodules are not developed; they appear only when it is grown in a suitably infected soil. Although not indispensable to the plant, the associate bacterial colonies appear greatly to favour its development. Leguminous plants cannot be grown many years in succession on ordinary land; yet at Rothamsted, on a garden plot, which probably was heavily manured in early days, clover grew well over a long period, though gradually the plot became patchy. It is a matter of common observation that, on waste land, a variety of weeds will flourish during the first two or three years, then suddenly these give place to wild-white-clover; in the interval there has been an accumulation of organic matter in the soil. The impression is growing that, to extend the period during which leguminous crops can be grown with success, it will be necessary to maintain a supply of organic elements in the soil and to considerable depths for the deeper-rooted types.

Carbohydrate material seems to be specially valuable. The precise nature of the process by which nitrogen is fixed is not known; it appears less strange than it formerly did, now that ammonia is manufactured on a large scale from nitrogen and hydrogen—but at a high temperature and under great pressure, whilst the plant system works quietly at the always relatively low temperature of the soil, at atmospheric pressure and in the dark. Probably, ammonia is formed initially in the plant by the action of hydrogen generated in a circuit of high potential, as the outcome of the oxidation of carbonaceous material, such as a carbohydrate would supply.

The extent to which the Jekyll and Hyde elements of the strange leguminous partnership function separately appears to depend on the condition of the soil. When the supply of nitrogen is abundant, either as nitrate or as an ammonia compound or in an easily assimilable organic form, the plant is able to function normally, as do other plants; but when these are lacking, the supernumerary organisms are drawn upon and forced into activity. The nutriment they supply is of a special kind, apparently. Probably the nitrogen is laid down initially in the form of a protein, the elements of which are duly translocated into the plant; to account for the increase of indican under the influence of the nodular growths, it is only necessary to suppose that among these elements one yielding indoxyl on reduction (such are known) is relatively abundant.

Mr. Davis is of opinion that, when wheat is grown with the indigo plant and the proportion of indican in the leaf is thereby materially increased, maybe to the extent of 50 per cent., the effect is due to the withdrawal of readily available nitrogen from the soil by the wheat, so that the nodules on the roots of the indigo plant are, as a consequence, forced more into action than would be the case if the plant had a larger store of assimilable nitrogen at its disposal. He is in no doubt as to the importance of a good supply of organic matter, yielding carbohydrate nutriment; also all important, in Bihar especially, is a supply of soluble phosphate: in short, the nutriment conditions must be those which favour the development and activity of the nodules; under such conditions the plant will flourish and be leafy.

It has yet to be ascertained whether indican can be formed, if the indigo plant be

grown without nodules; and, on the other hand, whether indican can be produced in the nodules alone. The formation of indican may be more a matter of the production of indoxyl than of the existence of a special mechanism (enzyme) in the plant, able to couple the indoxyl with glucose. It is noteworthy, in this connection, that indigo can be obtained from non-leguminous plants, *Woad*, for example.

Prior to Mr. Davis' study of the influence of wheat, Mr. Howard had pointed out that on Pusa soil, Pusa 4 wheat and the Java indigo plant could be grown together with advantage; but the general experience of planters who had tried the two together had been that, although a fine crop of wheat may be obtained, the indigo plant largely dies out. In Mr. Davis' opinion, though in some cases this may be due to the soils holding moisture badly, it is mainly because of the poor condition of most planters' soils, the amount of available phosphate being so small that it is used up during the growth of the wheat. He has, therefore, recommended trials on soils treated with superphosphate and either sannai or seet.

Remarkable results similar to those with wheat at Pusa were obtained by Mr. H. A. Inglis, at Bimhar, in the season 1919, by growing on one field the indigo plant with a cover crop of mustard and on another partly with mustard and partly with flax. In the one case, the field had been manured with seet in 1916-17; 15 maunds of wheat and 8 seers of indigo were then produced per bigha. After the indigo plant had been cut, the land was prepared (1918) and superphosphate spread on it at the rate of 2 maunds per bigha before sowing. As to the other field, part had been in fallow and was irrigated with seet water; the remainder had been in fallow and was irrigated with seet water; the remainder had not been manured during four years. The crops were very fine.

Although the total yield of plant per bigha was exceptionally high (over 250 maunds), far higher than is usual in Bihar, the quality of the plant grown with the cover crop was also high, so that the total production of cake indigo per acre amounted to 43 seers 10 chelaks from the one and 41 seers from the other field.

The results are summarised in Table IV.

The indigo industry has always been a migrant industry, fresh lands having been sought for when those used were exhausted.

Latterly a beginning has been made in Assam, where the plant can be grown with great advantage on newly cleared tea land and between the rows of young tea bushes. By trials made at Panchnoi, Mr. Leo West has shown that it is possible to obtain both a high yield and superlative quality of plant. Unfortunately the disastrous state of the tea trade has prevented development. Mr. Davis regards 200 to 300 maunds per acre for the whole season in Assam as a safe estimate; plant grown specially for mahai and cut at the proper time should contain about one per cent. of potential indigotin in the leaf. The seed from an acre would suffice to manure an acre of land; its use as a manure for tea would reduce the present very heavy outlay on nitrogenous manure; it is also an admirable manure for sugar cane. Possibly, the indigo plant might also be grown together with flax, of which there is now a great shortage.

In Bihar, at the present time, the average produce of Java plant is from 50-70 maunds an acre and the plant is of poor quality, yielding only 40-45 per cent. of leaf containing about 0.6 per cent. of potential indigotin. The cost of manufacturing indigo necessarily depends upon the yield per acre and it will not pay to grow it unless much better returns are obtained than at present. The primary need of Bihar seems to be an improvement in growth of the plant, so that a far higher return per acre may be secured. All other improvements are negligible in comparison with this, if the competition of synthetic indigotin is to be withstood. During the war, the necessary phosphate was unobtainable and supplies are still difficult to obtain at an economic cost; but the issue has to be faced, in view of the high value

of indigo seed as a quick acting manure. In Bihar, unseeded land which let at only Rs.20 per acre, after manuring with indigo seed could be let for tobacco-growing at Rs. 100 to 120; the development of tobacco in Bihar, in fact, has been due almost entirely, to the use of seed for manure. Now the crop that can be grown in Bihar is so poor that the seed from four to five acre of indigo land will only suffice for one acre. The question is one of expediency: whether it be desirable to raise the level of fertility or to maintain it at a low average.

During his stay Mr. Davis has visited a large number of factories in different districts and analysed more than 600 samples of their soil. The examination of these soils has thrown much light on the manurial requirements of the Tirhoot area. Apparently three distinct classes of soil exist in Bihar, which require very different manurial treatment for the best results. He defines these as follows:

1. The great majority of planters' soils in Tirhoot are deficient in readily soluble or "available" phosphate. In some parts of Champaran this is at present the only soil constituent which is badly deficient and when it is made good by manuring with superphosphate extraordinary increases of crop have been obtained (for example, Byreah, Rajpur, Lalseriah, Turkowlia). Soils which respond to superphosphate alone are found by analysis to be still comparatively well supplied with organic matter (humus)—these parts of Champaran were originally forest land reclaimed for cultivation comparatively recently, within the last 100 years. In these soils the limiting factor is deficiency of soluble phosphate and when this is made

good extraordinary increases of crop are obtained.

2. Most soils in Tirhoot outside Champaran, however, are very deficient in humus as well as phosphate and such soils only respond very partially to superphosphate alone. This class of soil is prevalent in the Mozafferpur district, even more so in Darbhanga and reaches an extreme limit in Monghyr. In some cases, in the last district, the soils are even more deficient in organic matter (humus) than in phosphate and manuring with this alone leads to but little increase. Thus at Munjhoul, some of the soils contain 0.1% or less of humus by the ordinary methods of analysis, whereas a minimum of 0.5% is generally regarded as essential for a fair growth of crops.

In many cases on actual planters' estates extraordinary improvement in the yield of indigo and of other crops has followed the combined treatment with sannai and super. In the case of indigo the yield of plant has been doubled and the produce brought up to 20 to 30 seers per acre or more.

This treatment, no doubt, will also prove beneficial in the case of sugar cane, the cultivation of which has recently been taken up widely and very profitably in North Bihar.

3. There is in North Bihar a third class of soil different from the preceding two classes. This type, instead of containing from 10 to 20 per cent. of lime (CaO) in the form of carbonate, as is the case in most of the soils of Tirhoot, is actually very deficient in lime. These soils are found in a strip of land in the Darbhanga district running through Benipore, part of Mangalgarh (Bagmutti alluvium) and also in the Bhagalpore district. Some of the Bhagalpore soils are deficient in phosphate as well as lime but those of the Darbhanga strip are usually well supplied with available phosphate.

Many of the soils of this third class are very stiff clays and intractable on this account unless ploughed at precisely the right moment. The intractability is probably due to deficiency of lime, which is only present to the extent of 0.1 to 0.5 per cent. and not in the form of carbonate. Such soils would, no doubt, be improved in texture by liming or by incorporating with them the highly calcareous soils of adjacent areas. Some of these soils are also deficient in organic matter.

Very different manurial treatment is required on different estates, according to the nature of the soil: (1) treatment with super alone; (2) treatment either with green manure (sannai) or with green manure combined with superphosphate; (3) treatment with lime alone or with lime combined with green manure or seet. Each planter will have to ascertain what are the requirements of his own particular soils.

In Mr. Davis' opinion, the importance of proper manuring in North Bihar cannot be overestimated it is the keynote to the prosperity of the indigo industry and ultimately of the ryots on small holdings, who depend largely on special crops, such as tobacco and chillies, grown on lands manured with indigo seet. There is no doubt that most estates have been greatly impoverished by lack of proper manurial treatment, especially since the advent of the high yielding Java variety of the indigo plant, which more rapidly strips the soil than other crops. The effect of proper manurial treatment is cumulative. By improving the yield of indigo from the present 50-75 maunds of green plant per acre up to 150-200 maunds per acre (which actual planters' trials have shown to be possible), the output of indigo seet is doubled and so a far more efficient manuring of rabi crops (cereals, tobacco, chillies, etc.), with correspondingly higher yields, becomes possible.

In the competition of indigo with synthetic indigotin, in the future, success will depend as much on the increase in the profit from other crops by manurial treatment as from an increased yield of actual indigo.

SELECTION OF PLANT.

Mr. Davis has established the fact that the percentage of indican in the leaf of the indigo plant may vary considerably in accordance with variations in the cultural conditions. There appears to be no evidence that the plant has deteriorated through cultivation in Bihar. The question has been raised, whether varieties which would afford a specially high percentage of indican may not be produced. It is clear that the inquiry into such a problem could not be profitably undertaken except under strictly comparable conditions of soil, which are not easily secured.

It is most unfortunate that the botanist appointed to deal with the problem practically, after but very brief inquiry into the matter on the spot, was led to think that

results of value were not likely to be obtained from selection work aiming at the production of a variety specially rich in indican. He, therefore, did not attempt the task. His reasons carry no conviction to my mind and his conclusions seem to me to be premature. Whatever the chance of success, the inquiry is one that must be undertaken, at an early date, on general grounds, in view of the success achieved with plants of other orders. Whatever the result, most important knowledge of the special behaviour of the leguminous plant will be secured. It is to be hoped that, ere long, a competent botanist may be found who will grasp this great opportunity, realising the importance of the practical issues at stake, in their general bearing on the quality of crops grown under the climatic and soil conditions of India; but he must not be a man who has had all imagination educated out of him.

SPECIAL VALUE OF LEGUMINOUS CROPS.

Finally, I would dwell upon the extraordinary value of an experimental inquiry such as Mr. Davis has initiated into the requirements of a leguminous plant so typical as that yielding indigo. Years ago Sir William Crookes aroused public interest by drawing special attention to the need of nitrogenous fertilisers if the world were to be kept supplied with wheat. Consequently, the advent of the method developed with such success in Germany, of late years, of making ammonia from atmospheric nitrogen and hydrogen liberated from water has been hailed with acclamation; yet it is a method involving much capital outlay and a considerable expenditure of fuel; even where water power is available the capital outlay is great. Nature's method of attracting nitrogen from the atmosphere has yet to be appreciated: at least, in the East, this method alone should be followed; the continued use of costly artificial nitrogenous manures is the outcome of the thoughtlessness and lack of observational and reasoning powers of which we have too long been guilty. We, in this country, make far too little use of leguminous crops—the intervals at which they figure in the rotation are far too long; but, it will be said, this is because they cannot be grown more often. Perhaps a lesson may be learnt from the indigo plant. The majority of our pastures are of the poorest quality as fatting lands and miserably starved of leguminous plants. We have to

bear in mind that clover is as meat, whilst the grasses are but as bread. Man cannot prosper, he can barely exist, on bread alone: neither can animals on its equivalent, grass. We know what to do to make our pastures be both bread and meat. On the noted sheep-fattening pastures of Romney Marsh the herbage is a luscious mixture of the youngest grass with clover—*of clover grown with a cover-crop of grass*. It has occurred to no one as yet to question whether the clover grown under such conditions have not a special nutritive value as compared with the plant grown alone. Not only is the clover grown together with grass but both are constantly fed from above, from the animal droppings, with nitrogen, which is a special tonic to the grass, with organic matter and with phosphate, both of which, we may suppose, specially stimulate the growth of the clover.*

The grass-versus-wheat controversy has greatly exercised the public mind of late years, the more because there is an under-current of feeling that our grass lands are often inferior and, as it were, meatless lands, yet the farmer has an instinctive love for them, an instinctive belief in their value. Everything is tending now to show the importance of quality as distinct from quantity in food. We, in this country, greatly need to improve the quality of our food, especially of our milk and butter—maybe of our beef and mutton, though as yet we only know that most of it is superior to the meat we get from abroad and that we should do well to raise far more of it at home. Our pigs, we do know, have in large part been imperfectly fed; and pig-meat is certainly much improved in nutritive value by grass feeding. Winter grass is poor feed for milch cows. Of the roots, the

*The sheep play an important intermediary part, which must not be overlooked, not only by keeping the grass young but by transferring the nitrogenous virtue of the clover to the grass and the organic virtue of the grass to the clover; doubtless the two plants also exercise a reciprocal underground influence of a similar kind. The neighbouring pastures on which the ewes are fed with their lambs until these can run alone are totally different in character: the species are the same but the growth is sparse and mature in appearance; there is, doubtless, a great withdrawal of phosphate, which is used in the production of bone by the fast-growing lambs; and fewer sheep are folded on the land. The return to the land is, therefore, less probably in all respects than on the fatting land: it would be interesting to obtain a balance sheet for the two kinds of pasture. The perfection of our old grass lawns is well known: if these could be studied in conjunction with the pastures of Romney Marsh, probably much would be learnt of profit to agriculture. Perhaps some day Oxford botanists will awaken to the fact that "All Flesh is Grass," as Sir Thomas Browne quaintly states in his *Religio Medici*, "not only metaphorically but literally; for all these creatures we behold are but herbs of the field digested into them or more remotely carnified in ourselves."

mangold is seemingly worthless in comparison with the swede, the milk made from it being deficient in nutritive power—and yet we grow and use the former far more than the latter. Of late years seedsmen have vied in producing giant varieties of roots, just as the horticulturists have sought for size in vegetables. Visitors to the Royal Horticultural Society's Shows are familiar with the wonderful display of vegetables by Sir Vicary Gibbs, in particular. But the onion has lost much of its savour, the turnip is all but tasteless, the "not too broad broad bean" has no breadth at all of taste, the tomato is becoming flavourless, etc. Such is the outcome of selection and intensive culture. It is the case of indigo grown on seed, apparently of quantity without quality. We need to pay heed to the lessons Mr. Davis has begun only begun—to draw from his enlightened studies of one poor leguminous plant and begin over again with all our crops.* All is not gold that glitters: we have been thoughtless and so academic in our science that workers are in no way sufficiently alive to the great practical lessons, the great practical issues, before their eyes: too much of the research work we are engaging in is vanity and vexation, in large part trivial and with no practical motive behind it. The differences in value of vegetable products are astounding—the lemon, for example, is a most active antiscorbutic, whilst its near relation, the lime, is worthless. These matters are of the greatest consequence to us all, now that we are beginning to be assured that our growth, our health, our susceptibility to disease are dependent on certain minor and, indeed, minute constituents of our food—that food is primarily of value by reason of its quality rather than of its quantity; and proportion counts. We need many things but we must have them in due proportion—so must the plant.

It were time that we made more use of our knowledge. Man lives not by phosphate alone, nor does the plant; and yet phosphorous is the nuclear element of all living matter and our primary need; sooner or later the nations must fight over its posses-

sion. That India is in sore need of phosphates is clear; yet religion and commerce combine to withdraw it from use. That bones should be so largely exported from the country as they are is striking evidence of the alarming ignorance that prevails on all matters of this kind. In a country that can easily start a new religion, a new religion should be founded: one based upon and requiring the reverence of bones and their proper sacrifice in due season to the soil. Our own position is almost equally bad. To make our meatless grass into good sandwich material we need, in the first place, to anoint it liberally with phosphate,* then clover will begin to flourish. Basic slag, we know, is a good material for the purpose and yet we are now spoiling this for agricultural use by an altered treatment in the steel furnace; all the other sources of phosphates are foreign. The problem is of infinite importance. The phosphatic stone Mr. Davis has set rolling in India may roll down even upon ourselves—is already upon us, in fact.

However little moss it may gather, it should force us to think and perhaps to realise the moral burden upon us to make more provident use of the fertilising materials at our door, of which there is so small and limited a store at man's disposal.

My object has been to make clear the immensity and importance of the problems before us in agriculture, especially in connection with leguminous crops. In view of their magnitude, it is the most serious reflection possible upon our intelligence that an industry peculiar to the East and particularly to India, undoubtedly in principle the root industry of its agriculture, of a lineage than which none is more ancient, should have no proper recognition and support. Mr. Montagu, in his recent speech to the House of Commons, spoke of the development of the industrial and agricultural resources of India as the one cure for the present situation. The special correspondent of *The Times*, writing from Bombay a few days later (March 14th), discussing the impressions of a four months' stay, drew urgent attention to India's industrial needs. Agriculture is the chief industry of the country, yet it is to be deprived of scientific aid when it is in sorest need of help.

* The only edible vegetable oil which is reputed to carry the fat-soluble advitant is *Arachis* or ground nut oil, the produce of a leguminous plant much grown in the Madras area. In view of Mr. Davis's observations the effect of varied cultural conditions upon the proportion of the advitant is worthy of study* may be this is connected with the nodular growths in the roots and conditions which favour their development would favour its production. The value of an edible oil, easily produced in large quantity, would be great.

*The extraordinary effect phosphate produces is well brought out in two photographs in the fourth edition of Dr. Russell's "Soil Conditions and Plant Growth" in the new series of Rothamsted Monographs.

Opportunities lost are not regained. To interrupt the investigation at its present stage is an act nothing short of madness. Mr. Davis has proved himself to be an exceptionally capable inquirer. That he would spare no effort and do honest and fruitful work I knew; but that he would show such unusual breadth of outlook and constructive ability I did not anticipate. My recompense, even at this melancholy moment, is the knowledge that I have been so justified of my choice.

DISCUSSION

THE CHAIRMAN (Sir Thomas H. Holland) said he doubted whether the author would have read the very interesting paper they had just heard were it not for the decision which had recently been taken to stop the research work carried on for the last six years by Mr. Davis, at Pusa. It was a bad budget which did no one any good, and the decision to stop the research work had apparently encouraged the author to gather together his ideas on the very interesting subject with which the paper dealt. The Government of India were faced this year with a deficit which exceeded that of the previous year, although last year's deficit had constituted a record in the financial history of British India. In such a time of financial stringency, therefore, one should not, without convincing reasons, urge on the Indian Government the duty of financing the research operations in connection with indigo in which Mr. Davis had been engaged. It could not be said, however, that the author made his demand hastily or without substantial justification. Personally, knowing something of the objects to which public revenue in India was being devoted, he was not prepared to dispute the author's contention; he believed there were even good financial reasons for continuing the research work, at any rate for some years to come. To stop the work at its present stage, when the foundation facts had been established and results of direct commercial value were beginning to be available, would mean the waste of money already well spent. That money, moreover, was not all obtained from the general public revenues; a great part of it could be obtained from a special export cess, which was readily borne by the trade and which was authorised by an Act passed in 1918 for the specific purpose of assisting scientific research work in connection with the cultivation and manufacture of indigo. It was possible that the sum so raised was not sufficient to cover the whole cost of the research work, at any rate during the last two years, when the production and export of indigo had fallen off to a certain extent, but that could easily be remedied by obtaining powers, either prospective or retrospective, to resoup the

relatively small sum temporarily lost by drawing on the income which increased exports in the near future would almost certainly yield.

He had been told that the area under indigo had recently been increased, partly as a result of Mr. Davis's experiments, and that next season the crop would greatly exceed that produced last year. It was not a case, therefore, of "spoiling the ship for a ha'porth of tar," because the Government was not asked to give the ha'penny, but only to lend it. If the requisite loan promised only distant and doubtful returns, there might be some reason for adding it to the other petty savings by which the Government hoped to tide over the present period of financial stress; but, in the opinion of those best able to judge, results of financial value, direct as well as indirect, would almost certainly accrue in the near future, if the work were not stopped at the present critical stage.

The author had summed up and confirmed, with the force of recognised authority and with a due sense of relativity, the evidence which the Industrial Commission obtained in 1916-17, from representatives of the various contributory interests—the agricultural chemists, the sugar and indigo planters, commercial men and even from intelligent consumers. He did not propose to detail the conclusions at which that Commission had arrived, because they had been extended and to some extent superseded, by the work the author had described that evening. The author had mentioned many important points which had been established as a result of the research work carried out. In the first place, it had been found that, acting as a soil fertiliser, indigo increased the yield of other crops with which it was grown in association or rotation. Amongst those crops were wheat and sugar. To take the case of sugar, the cultivation of indigo would probably help India to save a large proportion of the enormous sums of money now sent out of the country to pay for imported sugar. For a tropical country to import sugar from a temperate zone four thousand miles away, seemed as surprising as it would be for a Newcastle housewife to send to America for her domestic coal. The author had also referred to the fact that the increased consumption of food grains which was now being indulged in by some millions of Indian workers—the first direct result of the increase of wages following the war—had seriously reduced, if not actually obliterated altogether, the exportable surplus of wheat. The retention of those food grains in the country had meant that India's purchasing power had correspondingly depreciated. Any research work, therefore, which increased the fertility of the soil and accordingly reduced the competition for land between the forests and the agricultural crops (which was now beginning to be severe) added to the wealth of the country in the only way in which that could be done without introducing the accessory

evils which seemed to be the inevitable accompaniments of factory industries. The production for export of an expensive article such as indigo, instead of relatively cheap exports like wheat and rice, must ease the exchange difficulties correspondingly. The adverse balance of trade from which India had suffered since 1920, had added very seriously to the difficulty of paying her so-called Agency charges in sterling. The growing of more expensive crops meant that the land was used more economically, and would be, to that extent, of direct financial advantage to India; for that reason he thought one would be justified in urging the Government of India to reconsider its attitude in the matter. An assured output of natural indigo, moreover, was necessary for the full success of the indigenous textile industry, in which—including the mills and the hand loom weavers and spinners—something like three and a half million workers were engaged. All those workers were Indians, and were dependent on the industry for their livelihood. The textile industry was a flourishing one, from which the Government obtained a substantial revenue by direct taxation as well as returns in various indirect ways. An adequate production of natural indigo formed, as it were, an insurance against the monopoly dangers which might arise if the synthetic product completely replaced it; in other words, the cultivation of natural indigo as an industry was important, as a safeguard for the preservation of one of the largest Indian industries. The author regarded the suppression of the research work as involving a danger not confined to India alone. However, personally, he thought it was unnecessary at the moment to consider the Imperial question, because the danger was to India itself. It was not potential, but real; not problematic, but inevitable; not distant, but immediate. No synthetic indigotin was made in India, and no synthetic substitute for indigo would be made in India in the near future. By starving to death her natural indigo industry, the country was placing herself at the mercy of the foreign manufacturer. The Indian political leaders said they feared the English manufacturer as much as, if not more than, the German or American manufacturer; they had the Lancashire bogey always in mind. It was just possible that when India began to employ her new weapon of fiscal independence, she would find the English, American, Continental and Japanese synthetic chemists acting in most embarrassing, if accidental, union. He had been told that one reason why the indigo industry had been selected as a victim for economy lay in the recent change in the constitutional structure of the Indian Government machinery. It was asserted that the first direct results of the researches would benefit an industry largely controlled by British planters and commercial

houses, and that, therefore, the Indian members of the central Legislative Assembly, who now, for the first time, controlled the Government of India's budget, would regard with suspicion and almost certainly reject proposals for expenditure on work which was likely to benefit English commercial interests. If the Government of India were unable to state convincingly their reasons for incurring the small expenditure involved, which was probably but a temporary advance, it was just possible that the Legislative Assembly might commit itself to a decision as unwise as some of those which marked, or even marred, the proceedings of the maternal institution at Westminster. From what he knew, however, of the good sense of the Indian Legislative Assembly, and of the way in which it reacted to full and free information, he would be inclined to predict an entirely opposite result. In any case, the responsibility for that result should be placed on the body that had control of the purse. It was not fair to blame the Legislative Assembly for adopting a short-sighted policy when the facts had not been put before them, for although they could cut down they could not legally add to the budget proposals prepared by the Government of India itself. What were the facts that might be put before the Assembly in justification of an expenditure of the kind in question? The expenditure involved seemed to him almost negligible compared with that required for, say, a new University for the small city of Delhi, for which the Government had just placed a Bill before the central Legislature. He thought, moreover, that the expenditure of money on indigo research work at Pusa was quite as justifiable as similar expenditure on the cultivation of peaches in Baluchistan.

To what extent was it true that the research work at Pusa would benefit English interests? The cultivation of indigo by Indians was on a distinctly larger scale than that on plantations controlled by Europeans. If Indians did not turn the results of the research work to practical account, it would be the fault of their own Ministers, because under the new constitution agriculture was a transferred subject. The dye, too, was largely used by Indians in all parts of the country, and any evil results which might follow its replacement by the synthetic product would affect the textile mills, which were largely financed and controlled by Indians. It was natural to expect that the people's representatives in the Assembly would like to see Indians taking a larger share in the industries and prosperity of the country, but they were not foolish enough to destroy an industry which benefited thousands of Indian cultivators and formed an insurance for the large textile industry merely because a few score English planters grew indigo as well as sugar. Nor were they foolish enough to kill an industry which gave the country a valuable export

without involving the loss of those food stuffs which formed two-thirds of the poor man's budget in India. If the Legislative Assembly had definitely refused to guarantee for a short period only the cess collected—they were only asked to guarantee it—he thought the full facts could not have been placed before the members. The cess was not levied on indigo used in the country itself, but was paid by the foreign consumer in the form of export duty. If his friend Mr. Sarma, the member of the Government of India in charge of Agriculture, had not supported the claim made for indigo research work, he could only suppose the scientific members of the agricultural service must have stated their case very imperfectly to him, because he was too wise to neglect an opportunity of turning science to account in agriculture and too broad-minded to be misled by the false assumption that the results would be for the benefit of Europeans. On the facts it appeared that there had been a misunderstanding of a kind that proper representation should remove, and it would be for the benefit of India if the discussion at the meeting that evening helped the Government to re-open the question afresh. It had been suggested to him that the planters themselves, with the help of the great commercial houses behind them, might properly support the research station without any help from or intervention by the Government; but personally, he would not care to go before the Planters' Association or Bengal Chamber of Commerce with a proposal of that sort. The commercial community had already consented to an export duty in order to finance the research operations. The money so obtained, although paid ultimately by the consumer, was so much deducted from the profits of the producer and exporter, and to that extent they were handicapped in competition both with the synthetic product and indigo produced from other sources. No part of the cess was paid by the army of small dyers in India, who were mainly supplied by the small indigo growers of Madras, the United Provinces, and the Punjab. The European planter was able to take some advantage already of the research work which had been done. To some extent he was able to carry on experiments, though more expensively and less efficiently, in his own factory. The small Indian producer, however, could do neither of those things. His methods would remain just the same until the research work was relatively complete and the improvements could be demonstrated to him by the agricultural officials in ways more likely to impress him than monographs and pamphlets. The final results would affect him considerably, whereas he would get no advantage at all from work that had not reached a stage which justified demonstration by the ordinary subordinate agricultural officials. The planters who might continue the work in their own factories, being

sane business men, were not likely to publish their results or demonstrate their methods. It seemed to him, therefore, that the curtailment of the Pusa researches was likely to affect the poor Indian cultivator very seriously indeed. To ask the Planters' Association or the Bengal Chamber of Commerce to finance the work at Pusa for the benefit of the general public, was too much to demand of business men. They had already gone as far as wisdom justified in paying the cess on exports. In addition to that, the planters had suffered a great deal in Bihar from the mischievous activity of agitators, who stirred up racial animosity. English commercial men had not been encouraged recently to extend public spirit in a direction likely to be utilised by unscrupulous politicians. He was not referring to the Indian leader who represented his community in the Legislative Council, whose objects were perfectly sane and understandable and whose proposed reforms received the support of all enlightened Europeans, but to the man who, following Gandhi, objected to all improvements and progress because, and merely because, they were English in origin. It needed a very small number of such men, working on a credulous and ignorant population, to injure their own country as much as they injured the indigo planter. The indigo planter was perfectly well aware that if he, through altruistic motives, encouraged work of the kind in question, he might or might not receive the benefit from it himself. He did not make those remarks with the object of impressing Indian agitators, but to explain the attitude adopted by the English commercial men—planters as well as business men—in Calcutta. They had, in his opinion, gone as far as business men were justified in going in agreeing to the export duty on indigo.

He was tempted to refer to the scientific aspects of the question which the author had dealt with, and especially the employment of phosphates, but many distinguished authorities on the various branches of the subject were present and would probably like to join in the discussion, so that time did not permit.

DR. J. AUGUSTUS VOELCKER said that one thing had been made quite clear, namely, that scientific enquiry would play a great rôle in the future development of the indigo industry. The enquiries which had already been made appeared likely, in the near future, to lead to useful results. When he was in India, about 1890, the indigo planter was largely at the mercy of the people who posed as scientists rather than actually being such, and one could not be surprised that very much progress was not made at that time. He thought the first serious effort at an independent scientific enquiry was made by Mr. Christopher Rawson, who read a paper on the subject before the Indian Section of the Society in 1900. Since the outbreak of the war Mr. Rawson had

interested himself more in the synthetic product, and it was not until the author, with Mr. Davis, whom he introduced to the work, came upon the scene, that the problem was really thoroughly tackled in a way which gave hope of success in the future. From what those present had heard that evening, and from what they knew, he was sure they would very much deplore the giving up of research work in connection with indigo. The question at the present time, as in 1890, was the two-fold one of an increased production of crop and a greater out-turn of dye. The work done at Pusa did seem to hold out the hope of increasing the production through the use of phosphates. On the matter of out-turn of dye he was not qualified to speak, but he would much like to know to what extent manufacturers had taken up the various improvements that had been suggested. The enquiries which had been conducted had emphasised the need for the study of the growth of leguminous crops. As the author suggested, attention had been directed in the past more towards the growth of cereals as affected by leguminous crops, and the growth of leguminous crops themselves had been insufficiently studied. One of the first things that impressed him on going to India was that the Indian, although he did not call himself a scientist, knew a good deal more about the scientific side of agriculture than he was given credit for, as was shown by the fact that he practised, without knowing it, a regular rotation of crops which the best scientist could not improve on. It had long been thought that the leguminous crop collected nitrogen for the benefit of the corn crop, and that the ground was thereby enriched. The author had described the reverse of that process in his paper, and had shown that the growing of a corn crop-wheat, might benefit by taking the extra nitrogen out of the soil, so making the soil poorer and enabling the indigo to grow better.

MR. G. WATSON mentioned that since Mr. Davis's appointment the annual sum expended on indigo research work had not exceeded £4,000, half of which, up to the present year, had been paid by the cess.

MR. R. BRIDGETT said a good deal had been heard about the production of indigo and the advisability of producing it, but as a dealer and a merchant he would like to say something about the consumption side of the question. It was important to encourage people to wear clothing dyed with natural indigo: if there was a demand for any article production would follow as a natural consequence. There could be no doubt that most dyers preferred synthetic to natural indigo because it was easier to use; but if the public demanded that their clothes should be dyed with natural indigo the dyers would have to use it. The

largest users of blue cloth were the Government, for uniforms and police clothes. A long time ago the Government had a clause in their contracts insisting that natural indigo should be used, and the decline of the natural indigo industry dated from the time that clause was removed. A memorial, signed by many influential persons, asking for the reinstatement of that clause was presented to the Government in 1914, but without result. The railway companies were also large users of blue cloth, and if they could be made to see the advantage of having their uniforms and upholstery dyed with really good dye it would be one of the best means of helping the natural indigo industry. The demand to-day was all for cheap goods, including cheap clothes dyed with inferior dyes; if people would only buy good things, and good dyes that would last, it would be a great advantage to both themselves and the indigo trade.

SIR LANCELOT HARE, K.C.S.I., C.I.F., in proposing a vote of thanks to the author for his valuable paper, said he was very interested in the indigo question, because for five years he had been in charge of one of the principal indigo growing districts. He was sure those who opposed any assistance being given to the industry on the ground that a few English planters might benefit could not be aware of the enormous advantage the agricultural industry derived from the presence of a large number of intelligent planters, who carried on experiments and showed how better growth could be produced. The manner in which they looked after the ryots was also extremely beneficial. He would be very sorry to think that the indigo industry was going to be broken up and that the planters would have to go away from the district, as they had to go from Eastern Bengal. He had been interested to learn that experiments in the growth of indigo were being conducted in Assam. He was stationed in Assam for some time, and was sure that if the indigo industry could be developed there great progress would be made by the assistance which the large number of planters who were scattered throughout the province would give. He was also very much interested in the remarks the author made as to the possibility of developing, some day, a pure culture of the bacteria which produced the desired result, and of sterilising the wash, whatever it was. Such sterilisation had done a great deal of good in the production of beer and wines. He knew a little about that, because for some time he was in charge of the Excise Department in Bengal. Experiments which they made—principally with a view to taxation—showed the most extraordinary differences in the development of alcohol from the different washes, and it was found that that was due to the fact that the washes were not sterilised.

MR. T. D. CHADWICK, C.I.E. (Indian Trade Commissioner), in seconding the motion, said the author was one of the leading agricultural chemists, and his enthusiasm, vigour and breadth of view had been an inspiration to the chemists in India. He had given great praise to Mr. Davis, but personally he was sure that Mr. Davis would be the first to acknowledge that the fact that the author was watching his efforts had been a great stimulus to him. Mr. Chadwick on behalf of the Council and the Indian Committee, welcomed their Chairman that evening. Sir Thomas Holland had come from India with a very fine record of work done to help the industrial development of India, and it was very right and appropriate that he should take the chair at a meeting called to consider one of the oldest of Indian industries, which was both industry and agriculture.

The vote of thanks was carried unanimously.

PROFESSOR ARMSTRONG, in reply, thanked the Chairman for the very substantial and important contribution he had made to the subject, which would prove very valuable. He trusted something would be done but it would have to be done immediately, because only a few days ago he heard from Mr. Davis that not only was he leaving but the staff of Indian workers he had carefully trained was also under notice; he himself expected to leave about the middle of April. Reference had been made to the possibility of developing the use of pure cultures and sterilisation. That was by no means a distant hope, not only as the culture might be produced but because a very successful method whereby water could easily be sterilised on a large scale had recently been developed; on a small scale that process had already been found of considerable assistance in connection with indigo. A question had been asked as to the extent to which the improvements resulting from the research work had been applied in manufacture. The experiments had been carried out not on a small scale but at different factories and in some cases a very substantial benefit had already accrued. Mr. Davis had not dealt with the matter from a laboratory point of view but had gone to the planters and the fields; his work had been practical from the beginning.

The meeting then terminated

NEW GERMAN METALLURGIC PROCESS.

The attention of metallurgists has been attracted to a process recently invented in Germany which, it is declared, furnishes a simple, rapid, and effective method of separating alloys into their metal components and extract-

ing metals from mineral ores. This process is said to present many advantages over the method hitherto employed of melting alloys and separating metal components.

According to this process, writes the representative in Berlin of the United States Department of Commerce, the metals treated with the catalytic agent go into solution in a very short time, the treatment of big blocks of metal being effected in less than 30 minutes. Out of the solution thus obtained the various metals are dissected by the employment of simple methods of chemical reaction, which permit the retaining of the metals one by one. The product first obtained is in the form of a muddy sediment which, after being dried, yields a metal powder ready to be used or melted in crucibles, or to be treated by electrolytic process. Metals and concentrated ores can be treated in the same way, although they require one or two more operations than pure metal alloys. It is stated that the catalysator employed can be bought in the open market in any quantity required, the greater part of it being recuperated in the process and used again.

It is claimed that this process offers many advantages over the present methods employed. The general expenses involved are declared to be relatively small. The installation and appliances are quite simple. The elimination of the melting process does away with the outlay for coal for that purpose. It is further declared that the workmen necessary require no special experience. The process is susceptible of being employed on a large scale, quite a number of charges being treated at a time. The apparatus can furthermore be constructed to work continuously, being served in series by the same gang of workmen at the same time, thus reducing to a minimum the manual labour required.

It is asserted that the process is effective with any number of metal components, every metal being recuperated separately, and in the case of concentrated mineral ore every component metal part, be it silver, antimony, tin, lead, nickel, or copper, being retained one by one in the purest form.

The inventor of this process is an engineer of many years' experience. It further appears that he has developed a new process for the electrolytic treatment of metals, which is said to be much simpler than the methods hitherto employed. This new method enables one to procure copper wire directly out of the electrolytic bath, thereby eliminating the melting down of the electro blocks obtained under the old process, the rolling of the blocks into plate, and drawing into wire. It is claimed that this process accomplishes an immense saving in coal, wages, and time, and while some necessary improvements in the appliances remain to be perfected, the principal problem, it is said, has been solved in a most satisfactory way.

MEETINGS OF OTHER SOCIETIES FOR THE ENSUING WEEK.*

MONDAY, MAY 1. Royal Institution, Albemarle Street, W., 5 p.m. Annual Meeting.
Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. (1) Annual Meeting. (2) Messrs. J. J. Fox and A. J. H. Gauge, "The Determination of Tar Acids and Tar Bases in Drainage and Mud." (3) Mr. A. J. H. Gauge, "The Disposal and Purification of Flax Retting Effluents."
Farmers' Club, at the Surveyors' Institution, 12, Great George Street, S.W., 4 p.m.
Sir Henry Rew, "Local and Imperial Taxation as affecting Agriculture."
Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. J. O. F. Murray, "The Resurrection of our Lord Jesus Christ."
Electrical Engineers, Institution of (Western Centre), at the South Wales Institute of Engineers, Cardiff, 6.30 p.m.
University of London, King's College, Strand, W.C., 5.30 p.m. Dr. J. Hjort, "Biological Aspects of Oceanography." (Lecture II.)
At Bedford College for Women, York Gate, Regent's Park, N.W., 5.15 p.m. Prof. E. Claparede, "L'Intelligence et la Volonté." (Lecture II.)

TUESDAY, MAY 2. African Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Mr. C. F. Reg, "Abyssinia of To-Day."
Alpine Club, 23, Savile Row, W., 8.30 p.m.
University of London, King's College, Strand, W.C., 5.30 p.m. Dr. J. Hjort, "Biological Aspects of Oceanography." (Lecture III.)
At Bedford College for Women, York Gate, Regent's Park, N.W., 5.15 p.m. Prof. E. Claparede, "L'Intelligence et la Volonté." (Lecture III.)
Royal Institution, Albemarle Street, W., 3 p.m. Prof. Sir Arthur Keith, "Racial Problems of Africa." (Lecture II.)
Civil Engineers, Institution of, Great George Street, S.W., 6 p.m. (James Forrest Lecture). Sir John A. F. Aspinall, "Some Post War Problems of Transport."

WEDNESDAY, MAY 3. People's League of Health, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 6 p.m.
Public Analysts, Society of, Burlington House, Piccadilly, W., 8 p.m. (1) Messrs. J. Lizius and N. Evers, "Studies in the Titration of Acids and Bases." (2) Mr. A. Mitchell, "Graphites and other Pencil Pigments." (3) Dr. J. C. Drummond, "The Sulphuric Acid Reaction for Liver Oils and its Significance." (4) Messrs. W. Singleton and H. Williams, "Inadequacy of 'A.R.' Test for Alkalies in Calcium Carbonate."
British Academy, at the Royal Society, Burlington House, Piccadilly, W., 5 p.m. Sir Israel Gollancz, "The Merchant of Venice." (Annual Shakespeare Lecture.)
Archæological Institute, at the Society of Antiquaries, Burlington House, Piccadilly, W., 4.30 p.m. Mr. A. H. Thompson, "The Church and College of Catterstock, Northants."
Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 3 p.m. Annual Meeting.
Metals, Institute of, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. Prof. Sir Ernest Rutherford, "The Relation of the Elements."
University of London, at the Royal Society of Medicine, 1, Wimpole Street, W., 5 p.m. Prof. C. Winkler, "The Human Neo-Cerebellum." At Bedford College for Women, York Gate, Regent's Park, N.W., 5.15 p.m. Prof. F. Galdensperger, "Une Destinée Littéraire Anglo-Française: Alfred de Vigny." (Lecture I.)
Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. (Wireless Section.)

THURSDAY, MAY 4. Chadwick Public Lecture, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m. Sir Lawrence Weaver, "Rural Re-settlement and its Relation to Public Health." (Lecture I.)

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.
Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.
Mechanical Engineers, Institution of (North-Western Branch), Memorial Hall, Albert Square, Manchester, 7 p.m.
Linnean Society, Burlington House, Piccadilly, W., 5 p.m. Prof. Lloyd Williams, "The Life-history of Laminaria and Chorda."
Iron and Steel Institute, at the Institution of Civil Engineers, Great George Street, S.W., 10.30 p.m. Annual Meeting. (1) Presidential Address. (2) Mr. F. Clements, "British Siemens Furnace Practice." (3) Mr. D. E. Roberts, "Notes on Blast Furnace Filling." 2.30 p.m.: (1) Mr. H. C. H. Carpenter and Miss C. F. Elam, "Effect of Oxidising Gases at Low Pressures on Heated Iron." (2) Mr. C. R. Austin, "Hydrogen Decarburisation of Carbon Steels, with notes on related phenomena." (3) Mr. E. W. Ehn, "Influence of Dissolved Oxides on Carburising and Hardening Qualities of Steel."
University of London, at King's College for Women, Campden Hill Road, W., 4.30 p.m. Prof. V. H. Mottram, "Metabolism of Fat and Allied Substances." (Lecture II.)
Royal Institution, Albemarle Street, W., 3 p.m. Prof. E. B. Barton, "A Syntonic Hypothesis of Colour Vision."
Auctioneers and Estate Agents' Institute, 34, Russell Square, W.C., 3 p.m. Annual Meeting.
Chemical Society, Burlington House, Piccadilly, W., 8 p.m. (1) Messrs. I. E. Balaban and F. L. Pyman, "Bromo-derivatives of Glyoxaline." (2) Mr. E. P. Perman, "The Properties of Ammonium Nitrate. Part IV. The reciprocal salt - pair $\text{NH}_4\text{NO}_3 + \text{NaCl} \rightleftharpoons \text{NH}_4\text{Cl} + \text{NaNO}_3$." (3) Messrs. E. C. C. Baly and H. M. Duncan, "The reactivity of Ammonia." (4) Messrs. E. C. C. Baly, I. M. Heilbron, and D. P. Hudson, "Photocatalysis. Part II. The photosynthesis of nitrogen compounds from nitrates and carbon dioxide."

FRIDAY, MAY 5. Royal Institution, Albemarle Street, W., 9 p.m. Dr. M. Grabham, "Biological Studies in Madeira."
Engineers, Junior Institution of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. E. N. Ching, "Pressure Casting."
University of London, King's College, Strand, W.C., 5.30 p.m. Dr. J. Hjort, "Biological Aspects of Oceanography." (Lecture IV.)
At Bedford College for Women, York Gate, Regent's Park, N.W., 5.15 p.m. Prof. F. Baldensperger, "Une Destinée Littéraire Anglo-Française: Alfred de Vigny." (Lecture II.)
Iron and Steel Institute, at the Institution of Civil Engineers, Great George Street, S.W., 10.30 a.m. Annual Meeting continued. (1) Mr. D. Selby-Bigge, "Recent Developments in Power Production." (2) Messrs. A. Westgreen and G. Phragmen, "X-ray Studies on the Crystal Structure of Steel." (3) Mr. N. T. Bealew, "The Inner Structure of the Pearlite Grain." 2.30 p.m. (1) Mr. J. H. Whiteley, "Formation of Globular Pearlite." (2) Mr. A. F. Hallimond, "On delayed Crystallisation in the Carbon Steels: the Formation of Pearlite, Troostite and Martensite." (3) Mr. K. Honda, "On the Constitutional Diagram of the Iron-Carbon System, based on recent investigations." (4) Messrs. K. Honda and T. Kikuta, "On the Stepped Al Transformation in Carbon Steel during rapid cooling."
Chemical Industry, Society of (Manchester Section), at the Textile Institute, 16, St. Mary's Parsonage, Manchester, 7 p.m. Mr. N. A. Bellwood, "Progress of Oil Extraction and Kindred Trades."

SATURDAY, MAY 6. Royal Institution, Albemarle Street, W., 3 p.m. Prof. D. H. MacGregor, "Industrial Relationships." (Lecture II.)

Announcements intended for insertion in this list must be received at the SOCIETY'S Office not later than the Monday morning of the week preceding the Meeting.

£42,256 16 4

The above list includes all subscriptions received up to April 30th. Further lists will be published in the *Journal* from time to time.

Fellows of the Society are reminded that the amount aimed at by the Council is £50,000, which will enable them to renovate and decorate the House and make it more attractive and convenient.

*The three former lists were published in the *Journals* of December 2nd, 1921, and January 13th and February 24th, 1922.

NOTICES.

NEXT WEEK.

WEDNESDAY, MAY 10th, at 8 p.m. (Ordinary Meeting). MAJOR PERCY A. MAHON, R.A., LL.D., Sc.D., F.R.S., "The Design of Repeating Patterns for Decorative Work." SIR MARTIN CONWAY, F.S.A., M.P., in the Chair.

Further particulars of the Society's meetings will be found at the end of this number.

TWENTIETH ORDINARY MEETING.

WEDNESDAY, APRIL 25th, 1922; SIR JOHN F. C. SNELL, Chairman of the Electricity Commissioners, in the Chair.

The following candidates were proposed for election as Fellows of the Society :—

Ahuja, M. R., B.Sc., Amritsar, India.
 Bhan, S. N., B.Sc., Madura District, India.
 Curtis, S. Rumson, Newton Abbot.
 Duxbury, George C., Margate.
 Giffard, Edgar Osbert, Hove.
 Gillespy, George Thomas, A.M.I.Mech.E.,
 M.I.Mar.E., London.
 Horne, Robert Alexander, M.I.N.A., Rangoon.
 Lance, Ernest Solomon, A.M.I.F.E., Llandudno.
 Maartens, William Jacobus, Bloemfontein, South
 Africa.
 Mchta, Jehangir Merwanji, Bombay, India.
 Mehta, Manubhai Nandshankar, C.S.I., M.A.,
 LL.B., Baroda, India.
 Moss, Charles Samuel, Moose Jaw Sask.,
 Canada.
 Patel, Hormusji Dossabhoy, Bombay, India.
 Rowlandson, Major Charles William St. John,
 London.
 Saxona, M. Amba Prasad, Rajputana, India.
 Shank, John Verrall, Coorg, S. India.
 Sharman, Dr. B.D., B.A., M.B., M.R.A.S.,
 Calcutta, India.
 Shaw, Pran Krishna, B.A., Bengal, India.
 Verheyden, Dr. Cornelius, London.
 Verjee, N. M. Suleman, Mombasa, Kenya
 Colony.
 Woods, William, London.

The following candidates were balloted for and duly elected Fellows of the Society :—
 Morgan, N. L., B.Sc., Quebec, Canada.
 Pillay, G. Hurry Krishna, M.B.E., Rangoon,
 Burma.

Rayner, George Jabez, Victoria, British
 Columbia.
 Kamla, Pat Sahai, London.
 Starr, Mrs. Ida M. H., Easton, Maryland, U.S.A.

A paper on "The Use and Advantages of Electric Power in the Factory, as illustrated by its Application in the Jute Industry," was read by MR. JOHN FRANCIS CROWLEY, D.Sc., B.A., M.I.E.E.

The paper and discussion will be published in a subsequent number of the *Journal*.

INDIAN SECTION.

FRIDAY, APRIL 28th, 1922; SIR ROBERT WOODBURN GILLAN, K.C.S.I., LL.B., in the Chair.

A paper on "The Need for an All-India Gauge Policy" was read by MR. F. G. ROYAL-DAWSON, M.Inst.C.E.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

SEVENTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 22ND, 1922.

SIR ASTON WEBB, K.C.V.O., C.B., P.R.A., in the Chair.

The paper read was :—

THE LATE MR. HOLMAN HUNT'S EXPERIMENTS ON THE PERMANENCY OF ARTISTS' OIL COLOURS.

By PROFESSOR A. P. LAURIE, M.A., D.Sc.,
 F.R.S.E., H.R.S.A.,

Professor of Chemistry to the Royal Academy of Arts.

Of the work of painters of pictures in the first half of the nineteenth century, two from different schools, from the artistic point of view, have stood best the test of time, the pictures painted by the Pre-Raphaelites and the pictures by W. P. Frith and others of a similar manner.

Of the Pre-Raphaelites, Mr. Holman Hunt made continuous experiments on pigments and mediums, and through the kindness of Mr. Speed some of his experimental canvases have come into my hands.

There is, unfortunately, no record as to the history of these canvases, but I gather that they were hanging up or lying about in the studio, and it is quite obvious from their appearance that they have had every opportunity of collecting London dirt. It would not be fair, therefore, to record tests made under these conditions as proof that a particular pigment or medium was unreliable when used in painting a picture, and protected by varnish and also possibly by glass. Such information, therefore, as can be obtained from these canvases must be used with caution.

The first canvas, and the one of most interest is dated 7th May, 1860, and has written upon it "Canvas about the Colour of Parchment," "all without medium except where specified. C means copal, which in all cases causes the colour to be brighter, and sometimes is with the O.V. lighter in tone."

The pigments exposed are :—flake white; strontian yellow; lemon yellow; Naples yellow; cadmium yellow; yellow ochre; raw sienna; vermilion; Venetian red; Mars orange; Indian red; burnt sienna; Indian lake; burnt lake; cobalt yellow; chrome yellow; orange chrome; madder

yellow; Italian pink; crimson madder; madder carmine; carmine lake; Prussian brown; V.G. and cadmium; cadmium and emerald green; oxide of chromium; chrome green; emerald green; Veronese green; emerald oxide of chromium; verdigris; cobalt blue; French ultramarine; blue mineral; laques robert; Prussian blue; cadmium yellow; and a certain number of others which I have not been able to interpret.

The first remark to be made about this canvas is that all the pigments have gone down very much in tone, and that this darkening in tone has no relationship to the fugitive character of the pigment itself, but seems rather to have depended upon the transparency of the pigment, the opaque pigments having stood up best. The canvas has also become a dirty dark grey in colour. Now it is evident that this lowering in tone may be due to three causes:—the collection of dirt on the surfaces, a change in the pigment itself, and a darkening of the oil.

To deal first with the question of dirt:—If the pigments are washed with a neutral soap there is hardly any improvement in their appearance, and when examined under the microscope black particles are to be seen ingrained in the oil surface. This confirms the observations I have made before that the sooty particles of our modern towns seem to eat into and become ingrained in a linseed oil surface if it is not protected. An alkaline soap will remove this sooty layer restoring some of the brilliancy of the pigment, more especially in the case of opaque pigments, but doing little to brighten such a pigment as cobalt blue. It is also noticeable that on the whole the brilliancy of a pigment has been better preserved where mixed with flake white. Chinese vermilion is practically completely restored to its brilliancy by being washed with the alkaline soap, while cobalt blue is hardly improved at all, and chrome yellows only partially improved. The brilliancy of the flake white is completely restored, and the canvas recovers its original parchment tone. It is necessary to point out that special precautions have to be taken in washing with the alkaline soap, and special conditions adopted during the treatment.

An examination under the microscope of fragments of the more transparent pigments reveals the fact that the oil has become brownish yellow in tone, and the analysis of a portion shows that the oil contains

lead driers. I suggest, therefore, as an explanation of the lowering in tone, which has taken place beyond and apart from dirt, that there has been a slow action of sulphuretted hydrogen on the lead driers which has darkened the oil. In the case where lead compounds are present in excess, such as flake white, the treatment with the alkaline soap restores the brilliancy because on account of the enormous excess of lead compounds present, the sulphuretted hydrogen has not been able to make more than a superficial attack. But in the case of a pigment such as cobalt blue there has been nothing to protect the lead driers from being attacked, and the consequent darkening of the oil in the case of such a transparent pigment has lowered the tone throughout the mass and it cannot be restored by superficial washing. This view is confirmed by the fact that the flake white is bleached by peroxide of hydrogen.

When allowance has been made for both the ingrained dirt and the darkening of the oil, we have next to ask ourselves whether the pigments themselves show change. This is obviously a somewhat difficult question to answer, but I will do it to the best of my ability. The madder yellows have disappeared. This is a preparation which has rightly long disappeared from the artist's palette, and Italian pink and crimson lake are also gone. Burnt lake has stood the test of time better, and Indian lake has changed much less than I expected. The madders have stood the test of time perfectly.

With the earth colours, allowing for the darkening of the oil, I do not think there is any other change, though I feel somewhat doubtful about the raw siennas which seem to be very dark in tone. Cobalt blue, blue mineral, which is an artificial ultramarine, and Prussian blue have all stood well, and other specimens of artificial ultramarine have also stood, with the exception of one sample labelled French ultramarine, which seems to have gone a bluish grey in tone. A green made apparently from cadmium yellow and Prussian blue has stood well. The oxide of chromium green, emerald green and Veronese green have all stood well, but mixtures of emerald green and cadmium have of course gone black. Verdigris has stood up much better than we might have expected. The vermilion is unchanged. All these results agree with the conclusion as to the safe

and unsafe pigments which are the outcome of experiments by Abney, Church and other observers.

We come now to more difficult and doubtful ground when we examine the yellows. The orange chrome has stood well. The samples of cadmium yellow, with one exception, have stood well. The chrome yellows have got distinctly greener in tone, and aureoline or cobalt yellow has gone a dirty brown in some places.

To deal first with the chromes, I have found specimens of chrome yellow on Constable's pictures which are as perfect as the day they were put on, and it is therefore difficult to say whether we should blame the pigment for the change of tone that has taken place on this canvas.

With reference to the cobalt yellows, there seems to have been a rising of oil to the surface which has got blackened with dirt, and it is also quite possible that sulphuretted hydrogen has had an injurious effect on this pigment. The experiments by Captain Abney proved it to be quite permanent in water colour, and therefore it is a little difficult to explain its apparent bad behaviour in oil. It evidently must in the meantime be placed on the list for further enquiry and it would be of interest to get information from artists who have used this pigment for a considerable period. It has so long been among the selected yellows in the artist's palette, that I doubt the conclusions to be drawn from this result.

With reference to the cadmium yellows there are other canvases of Mr. Holman Hunt's on which cadmium yellows appear, including this one, which have stood the test of time, but in one case on this canvas the cadmium has completely gone. It is labelled cadmium No. 1, and is, I imagine, a pale variety. I have long held the opinion that while the mid and orange cadmium are perfectly stable, the pale varieties are open to doubt unless they are manufactured by a process which necessitates their being raised to a temperature of some 500° or 600° C., in which case I believe them to be perfectly stable.

Strontian yellow and lemon yellow seem to have stood fairly well. The sample labelled Naples yellow is difficult to report on without a knowledge of the original tint. The only information given is that when put on it was lighter than the canvas. As is well known, what is called to-day Naples yellow is not the old oxide of antimony
